THE fog of London and of other large towns, it is probable, presents to the minds of the majority of those who suffer from it an idea not much less hazy than the aspect with which it confronts and bewilders their sense of vision. Comparatively few of the afflicted care to inquire into the composition of their tormentor, or even to define its cause with accuracy. They may be aware that it is not all river damp, nor yet all smoke; but the subtleties of chemical analysis, however interesting to the professional inquirer, are for most men lost in a general feeling of present discomfort, which is tangibly aggressive, unfathomable, and unavoidable. Sir Douglas Galton, however, is not one of those who accept the mystery as such, and still less is he disposed to let ill alone and endure what has not yet been cured. At the Parkes Museum a few days ago he discussed at some length the composition, origin, and practical treatment of this master evil of town life. Fortunately his discourse did not partake of the nature of its subject; but, after traversing the details of theory, he was able to point his hearers to certain definite facts of causation, and to advocate remedial measures, which if carried out would doubtless prove to a certain extent effectual. According to Sir D. Galton's estimate, the fog-laden air of London contains four times as much carbonic acid as its ordinary atmosphere. It has been proposed to meet the difficulty by substituting the use of gas for that of coal in cooking and other domestic operations. To some extent this change has been carried out, and we shall probably see it in still wider exercise. A considerable period must elapse, however, before the open fire is done away with in favour of a stove—if, indeed, that day should ever come.

THE REGISTRATION OF PLUMBERS.

AT a dinner of the Company of Plumbers on Dec. 1st, the Master, Mr. F. Machin, was able to give a very satisfactory account of the progress which the Company had made in the examination and registration of efficient plumbers. During the two years in which this duty had been undertaken, as many as 1185 different craftsmen had been registered, the efficiency of these plumbers having been established after careful scrutiny of evidence tendered, the examination of certificates and indentures, and even after absolute practical examination. As many as 753 of the successful candidates were journeymen, many of whom were employed in all parts of the country. With a view to extending this movement to the provinces, local organisations had been formed, and every care was taken to ensure that no local bias should prejudice any candidate. Sir James Paget, in proposing the toast, "Prosperity to Technical Education," dwelt upon the decadence of the system of apprenticeship, and pointed out the need for it to be replaced by technical education, which was spreading over the whole country, and of which the Company had been one of the chief promoters. The progress of science and discovery, he said, had been so great that it was impossible that a man who had been instructed a quarter of a century ago could himself instruct

Digitized by Google

an apprentice now in all that was necessary in the course of one profession. The dinner was well attended, among the guests being several medical officers of health. We hear with pleasure of the progress of this movement. The relation which exists between disease and house conditions is daily becoming more recognised, and the main difficulty which has to be overcome is that of the dearth of artisans competent to carry out work in a manner in accordance with the requirements of health. Only recently we have heard that the death of Lady March has been attributed to her having slept in a bedroom which was adjoining a bath-room in which was found an untrapped drain communicating with the sewer. Under good bye-laws and with efficient workmanship calamities such as these in newly built houses would be impossible. But there is still much to be done in the reconstruction of old houses, and there is the greater need for the technical instruction of persons engaged in plumbing and the allied trades.

TREPHINING IN EPILEPSY.

ALL cases of successful cerebral surgery are at present of considerable interest, especially those cases in which procedures are taken for the relief of epileptiform convulsions. In the case which Dr. Oliver of Newcastle-on-Tyne has recently recorded, the interval of time which has elapsed since the operation was performed without the recurrence of the epileptiform seizure makes it probable that the relief afforded by the operation may be judged complete. In this case the epileptiform convulsions came on about a fortnight after an injury to the head in a young and previously healthy lad. After their first development he suffered from them almost daily, whilst he also complained of a painful spot on the right side of the head, a little above and anterior to the ear, which always became more painful just before and often soon after a fit. After a more severe fit than usual the patient would remain powerless for two or three days, as well as being deaf and unable to speak. In these severe attacks it was noticed that the convulsions were more marked on the right than on the left side. Medicinal treatment having been giving a fair trial, it was determined by Dr. Oliver, after consultation with his surgical colleague, to trephine the skull over the painful spot. The moment the bone was elevated the dura mater pressed up through the wound, becoming extremely tense. An incision was then made, and a few teaspoonfuls of serum containing shreds of fibrin gushed out. The membranes and surface of the brain were quite healthy. For about a day after the operation serum continued to escape from the wound in the dura mater, amounting in all to about two or three ounces. Two or three fits occurred on the day of the operation and the day subsequent to it. By degrees, however, days, then weeks, and latterly months, passed without the occurrence of any fit at all. Afterwards the patient was engaged as a clerk, and was confined in a heated atmosphere and had long hours at business. One evening, after a period of six months, he had a fit, but without loss of consciousness, and for a few days after this he had some minor seizures, but these speedily yielded to treatment, and for a period of six months, the date of Dr. Oliver's report, no fit of any kind has again recurred. A somewhat similar case has also been under our observation, in which, however, the epilepsy developed gradually after trephining for a traumatic injury. On opening the wound, a spicula of necrosed bone was removed, and afterwards the convulsive seizures gradually disappeared. It has been urged by some, however, that though some present relief may be gained for a time, the convulsive seizures return sooner or later. However that may be, and a wider experience must be acquired before the point can be definitely settled, still to have obtained almost a complete immunity from attacks that were rendering life a burden to the patient, and even threatening to shorten existence, was a great success; whilst the fact that in Dr. Oliver's case the patient was able to employ himself in such a responsible situation as he did, and for so long a time, leads us to think that, in this case at least, a permanent cure may have been effected.

WORKING HOURS ON THE RAILWAY.

IT is a matter of notoriety that some of the most pronounced examples of overwork have been, and continue to be, furnished by the experience of railway *employés*. That accidents occur from time to time which are more or less directly attributable to mismanagement in this particular is not remarkable. The wonder rather is that we do not oftener hear of them. We are not ignorant that on the railway the observance of a settled scale of working hours is at times a somewhat difficult matter. The length of journeys, unexpected delays from weather and the like, the utility of special aptitudes possessed by particular men and required at a given time, are some of the circumstances which may render the due allotment of time for purposes of work a matter for careful consideration. When, however, we find men employed on trains in the most responsible positions for more than thirty hours at a stretch we are surely justified in crediting their superiors with most culpable negligence. Necessity is said to have no law, and on this principle it seems to be assumed that the driver of a locomotive should be virtually a part of his machine. We fail to see the point, and the public, we are assured, will hardly allow that the personal risk which they incur by such a proceeding can be excused by the maintenance of a solid dividend for the benefit of shareholders. What is wanted is a larger staff of subordinate officials, who shall be available to relieve one another at reasonable intervals. An ordinary working period of twelve hours per day is, we take it, sufficiently long for this class of workmen, as well as for artisans engaged in other occupations.

EXTIRPATION OF THE LARYNX.

AT a recent meeting of the Berlin Medical Society, Dr. Hahn gave a demonstration of specimens of laryngeal carcinoma from cases in which he had excised the whole or a portion of the larynx, and at the same time summed up the ultimate results of his operations. He had performed extirpation, partial or total, in fifteen cases. Two of these are to be considered as cured; one was operated upon seven years ago, being then sixty-nine years of age, and he is still living and well. The operation involved the removal of the cricoid cartilage, the greater part of the thyroid, and part of the hyoid bone and epiglottis, the disease being one of carcinoma keratodes. The other patient was operated upon in May, 1886; here the disease was limited, and the removal confined to one-half the larynx. Dr. Semon, under whose care this patient is, wrote to Dr. Hahn that a small prominence had appeared at the site of the tracheotomy wound, which it is hoped is only a keloid of the cicatrix, but it would of course be carefully observed. A later report from Dr. Semon said that it had undergone no change. Of the remaining cases, there was only one of which Dr. Hahn had no recent information but the last accounts were very unfavourable. All the others were known to be dead; but it must be remembered that in all the cases, with the exception of the one alluded to above, the operation had been resorted to late in the course of the disease. He had that day (Nov. 16th) operated on a patient only thirty-six years of age, the youngest of his cases, whose ages ranged from forty to sixty-nine—mostly over

Digitized by Google

forty years. This patient had been suffering from laryngeal trouble for a year, and had been under the care of Dr. Krause. The diagnosis of carcinoma was made by the microscope, and a unilateral excision was performed. (On the 28th Dr. Hahn reports that this case was doing well.) Amongst the preparations which Dr. Hahn showed at the meeting was one where there had been nine previous operations for recurrence of the growth within the space of eighteen months; yet even to the end the lymphatic glands were never involved in this case. Indeed, he remarked that lymphatic infection is unusually late in laryngeal cancer. The most favourable cases are those of carcinoma keratodes; the least, the softer and infiltrating forms. The latter cases had better not be treated by excision of the larynx, but reserved for tracheotomy when occasion arises.

THE ALLEGED CANCER BACILLUS.

THE grounds adduced by Dr. Scheurlen in support of the contention that he has discovered the cancer bacillus were stated in his communication to the Verein für innere Medicin on the 28th ult. The material employed consisted in specimens of mammary cancer removed at operations, and in some post-mortem specimens of cancer of the breast, uterus, liver, and other parts. The tumours were washed in sublimate solution, and the "cancer juice" scraped off the freshly-cut surfaces by means of a sterilised knife. The culture media included pleuritic serous fluid, agar-agar, gelatine, and potato, which were inoculated in the usual way. The bacterial growth was very rapid, forming colourless films on the surface of the fluid, these films gradually assuming a brownish-yellow colour. They were found to consist of bacilli 1·5μ to 2·5μ long by 0·5μ wide, long ovoids, and spore-bearing. They stained readily with various reagents. No bacilli were found in sections of the tumours, but in cover-glass preparations of the "juice" they occurred, some of them within the cells. Six bitches were inoculated in one of the mammary glands, and in two which had died swellings had formed at the seat of inoculation, which swellings consisted of granulation cells and epithelioid cells, together with the bacilli. In the discussion on the paper, Dr. P. Guttmann believed that the case had been proved, but Dr. A. Fränkel criticised it adversely, pointing out that the very rapid growth of the bacilli was against their pathogenic character, and that degenerate cells formed a favourable nidus for bacterial contamination.

THE TOXIC ACTION OF PUTREFACTIVE MATTER.

DR. KOSOROTOFF has been engaged in making researches on the toxic action of putrid substances in Prof. Pashutin's laboratory, and publishes an account of his observations as a "preliminary communication" in some recent numbers of the *Vrach*. Cultures of bacterium termo were prepared from infusions of meat and of kidney beans. With these carefully sterilised saline solutions containing acetate of ammonia, phosphate of potash, sulphate of magnesia, and chlorate of potash, as used by Naegeli, were sown under four distinct sets of conditions. In the first series air was made to bubble constantly through the solution. Here a change was soon apparent, the solution becoming opalescent in ten or twelve hours and quite opaque in twenty-four hours. In the second series the tubes were covered with blotting-paper and were agitated daily. Here the microbes developed, but much more slowly than in the first series. In the third and fourth series air was rigidly excluded, with the result that no opalescence was observed till the fourth or sixth day. Experiments were first made with the microbes themselves, which were injected under the skin and into the veins of dogs. No injurious effects, local or general, were produced. The saline solutions in which the microbes had developed were then introduced in like manner into the circulation of animals. A marked difference was observed between the behaviour of the solutions to which air had had access and those which had been kept closed up. Thus, dogs into whose veins the first or second series of solutions were injected suffered from pyrexia, dyspnœa, vomiting, and diarrhœa with watery or bloody stools; but the general appearance of the animal and the condition of its nervous system was but little affected. The lethal dose of a solution which had been kept for from two to four weeks was ten cubic centimetres per kilogramme of weight. The post-mortem appearances were those of hæmorrhagic gastro-enteritis, with ecchymoses on the serous membranes and some fulness of the cerebral vessels. Under the influence of solutions in which cultures had been developed without access of air, a very different set of symptoms was produced. The animals became at first restless and excited, and afterwards fell into a typhoid condition, being unable to stand, the pupils dilating and consciousness being lost. The temperature fell, sometimes to a considerable extent. All the cases proved fatal, though in some only a very small quantity of the fluid was injected into the veins. The post-mortem examination showed a remarkable fulness of the vessels of the brain and its membranes, with extensive ecchymoses of the latter. Dr. Kosorotoff came to the conclusion that the toxic matter was soluble in alcohol as well as water, and that it was a poison in a chemical sense, not an infectious contagium. He considered, too, that it must be due to synthetic rather than to decomposing action on the part of the microbes.

THE PENDJEH SORE IN SOUTH RUSSIA.

DR. ZVIAGINTSEFF, of Kherson, in South Russia, has met with some cases of cutaneous ulceration which appear to be identical with the disease described by Russians as "Pendjeh sore,"[1] and which is doubtless of the same nature as "Aleppo evil," Baghdad "date mark,"[2] Delhi boil, Lahore sore, &c. Dr. Zviagintseff employed a corrosive sublimate solution for washing the sores, and dressed them with iodoform powder and ointment, a layer of cotton wool being applied over all. In this way they gradually improved in appearance, and finally healed with a dark cicatrix. No bacteriological observations seem to have been made. Auto-inoculation gave a negative result. Dr. Pierson, of the Indian Medical Service, has remarked[3] that this sore is known under different names all along the north-western frontier. His experience was that the only effectual treatment was to apply nitric acid freely to the sore, and to open the small surrounding "nests" with the lancet, putting a tiny drop of concentrated nitric acid into the openings. He also calls attention to the fact that when these sores have existed for a long time they have a permanent dull-brown stain, which renders them liable to be mistaken for syphilitic ulcers.

SMALL-POX AT LEICESTER.

WE are informed that the unvaccinated child whose case was the most serious in the recent outbreak of small-pox at Leicester is now doing well. Four other members of the family in which the disease appeared have been placed in the quarantine wards, one of whom has developed an abortive attack, and another on the 7th inst. showed what are feared to be premonitory symptoms. A few other persons in the town known to have been in the infected house are under strict surveillance and daily observation. One of these had also on the 7th inst. some suspicious malaise, pyrexia, &c., but there is not as yet any certainty whether the case will prove to be one of small-pox.

H.I.H. THE CROWN PRINCE OF GERMANY.

IT is stated that the physicians in attendance upon the Crown Prince are giving a trial to the treatment suggested by Dr. Freund of Vienna, and based on his analyses of the blood of patients suffering from cancer which showed an excess of sugar. By a rigid exclusion of sugar from the diet, and the substitution of saccharin, it is attempted to reduce the amount of sugar in the blood, and by that means to prevent the malignant growth. Dr. Freund's views have not won general acceptance, and one fact which is strongly adverse to them is that the subjects of diabetes mellitus are not specially liable to be attacked by cancer. We are glad to learn that there has been an improvement noted in the Crown Prince's condition during the last fortnight, and we hope it may continue. The period of improvement corresponds with the adoption of Freund's treatment, and very naturally this has excited hopes that a further continuance of it may be attended with still greater success. Too much stress must not be laid upon daily bulletins in such a case. The daily variations are difficult to appreciate, and the desire to detect improvement is very strong. More trustworthy results are obtained when the progress of a case is tested by careful examinations of the local changes at intervals of two or three weeks.

THE LIQUOR AMNII AND FŒTAL NOURISHMENT.

DR. OPITZ of Chemnitz, in reply to Dr. Ott, who holds that the liquor amnii is concerned in the nutrition of the fœtus, brings forward a case of malformation which is preserved in the museum of the municipal hospital in Chemnitz, which seems to show that the nutrition of the fœtus must be independent of the liquor amnii. An apparently healthy and well-formed child was born, which respired normally and passed meconium and urine. It also sucked, but immediately brought up the milk in a frothy condition. A gum-elastic catheter was introduced into the œsophagus, but it could only be passed as far as the cricoid cartilage, consequently some obstruction of the œsophagus was diagnosed. The child lived six days. At the post-mortem examination it was found that the œsophagus ended abruptly in its middle third. The stomach was filled with meconium. A fine probe could be passed through the cardiac orifice into the trachea.

BIRMINGHAM MEDICAL INSTITUTE: POST-GRADUATE LECTURES.

THREE courses have been arranged for the present winter session. The first of the series, consisting of three lectures on some of the Diseases of the Skin, was delivered by Dr. R. M. Simon, at the Institute, during the month of November. The lectures were illustrated by plates, microscopic specimens, preparations used in treatment, and by the exhibition of living cases. The attendance was very good, and afforded evidence of the satisfactory treatment of his subject by the lecturer.

HEREDITY AND NURTURE.

IN his second lecture at South Kensington, Mr. Francis Galton concerned himself mainly with the limits to the inheritance of ancestral peculiarities, and to the hereditary transmission of disease. He employed a metaphor of vegetation on two islands spreading over adjacent islets, to illustrate family likeness and family differences, stability of type in a population, silent transmission of ancestral characteristics, and blended and mutually exclusive heritages. He explained how laws of inheritance enable us to forecast "schemes" of children, grandchildren, nephews, &c., but do not accurately determine the place of individuals in their respective schemes. In this connexion he exhibited two interesting mechanical arrangements, by means of which the probable heights of male or female children could be determined from the known heights of the parents. In conclusion, he showed the close agreement between the results obtained by himself and by Dr. Reginald Thompson as to the numerical valuation of heredity in the production of phthisis.

PASTEUR'S METHOD SIMPLIFIED.

DR. HÖGYES of Buda-Pesth has published in the *Orvosi Hetilap* an account of some researches he has made on the protection of dogs from rabies by a somewhat simpler method than that employed by Pasteur. He, too, makes use of the spinal cord of an infected rabbit, but instead of drying it to a gradually increasing extent to obtain various degrees of activity, he merely rubs it up with water containing chloride of sodium so as to make solutions varying in strength from 1-10th to 1-5000th. The dog to be protected is injected successively with these, beginning with the weakest. The results appeared to be quite satisfactory, and a complete immunity from rabies to be secured by six of these injections.

ROYAL CORNWALL INFIRMARY.

We regret to learn that the Royal Cornwall Infirmary at Truro still remains without a physician on its staff. About two years ago, on the occurrence of a vacancy, Dr. Williams was appointed to fill the office; but in a short time he resigned it owing to a misunderstanding between himself and the house committee respecting the selection of in-patients. No steps have since been taken to provide the institution with a physician, which must surely be not only a distinct disadvantage to the infirmary itself, if not in direct violation of its bye-laws, but also indirectly a loss to the district.

DIPHTHERIA DURING PREGNANCY.

DR. KOROTKEVICH mentions in the *Russkaya Meditsina* the case of a peasant woman in the fifth month of pregnancy who was attacked by diphtheria during an epidemic which prevailed in the early part of the present year. A child of hers died of the disease. She was treated by means of local applications of salicylic acid and benzoic acid, and recovered in nine days. She was confined at term of a weakly boy. Dr. Korotkevich has only been able to find four cases of diphtheria during pregnancy reported, one by Olivier and three by Dr. Sochaff, who published a paper on the subject in the *Vrach* in 1883.

DEATHS OF EMINENT FOREIGN MEDICAL AND SCIENTIFIC MEN.

THE deaths of the following foreign medical and scientific men are announced:—Dr. Karl Dantscher, formerly Professor of Anatomy in the University of Innsbruck, at the age of seventy-five.—Dr. Johanes Nicolaas Ramaer, a distinguished Dutch alienist.

THE PERSPIRATION.

THE result of elaborate research made by M. Peiper yields the following conclusions: The perspiration is more concentrated on the right side of the body; this observation is in accordance with that of Reinhardt; it would be interesting to know whether the opposite was the case in the left-handed. The palm of the hand sweats four times more than the skin of the chest, and the cheeks one and a half times as much. There is a slow increase in the sweat in the afternoon, especially obvious from 8 to 12 o'clock at night. After midnight there is a diminution. Feeding has but little influence on this function. Elevation of the surrounding temperature increases

Digitized by Google

the perspiration, and variations of the hygrometric state of the atmosphere have an immense influence on the function. The quantity of water evaporated in a quarter of an hour from a cutaneous surface 25 centimetres square, in a normal individual, is about ·176 of a gramme. In infants the quantity is generally less than in adults. The weight of the body and sex have no marked influence on the perspiration.

THE OPERATIVE TREATMENT OF PERITONITIS.

DR. TRZEBICKY, writing in a Polish journal on the operative treatment of peritonitis, details experimental researches on sixty-seven dogs. From these he concludes that operative treatment s indicated in cases of purulent or septic peritonitis; that the employment of different antiseptic substances leads to results differing from one another. The most suitable liquid for washing out the peritoneal cavity appeared to be a solution of salicylic acid. The greatest care is necessary in cleansing the abdomen externally before the operation is commenced. Dr. Trzebicky does not find it easy to explain the variations in his results, but about the facts he has no doubt.

PATHOLOGICAL SOCIETY OF LONDON.

A SPECIAL MEETING of this Society will be held on Thursday, December 15th, at 8.30 P.M., to receive from Professor Crookshank a report upon an investigation into a Disease of Cows and its relation to Scarlatina in Man. The subject is likely to excite considerable discussion, and many new and important facts are, it is said, to be brought forward.

INFECTIOUS DISEASES COMMON TO MAN AND THE LOWER ANIMALS.

THE next meeting of the Epidemiological Society, which will be held on Dec. 14th, will be one of especial interest, Dr. Klein having promised to read a paper on some of the Infectious Diseases common to Man and the Lower Animals. We understand that the address will be illustrated by the exhibition of numerous microscopical preparations, and we presume that the more recent observations referred to in the reports of the Medical Officer of the Local Government Board will be discussed.

CARBOLIC INJECTIONS IN MALIGNANT PUSTULE.

DR. USPENSKI mentions in the *Meditsinskoe Obozrênie* that he has treated eleven cases of malignant pustule, with only one death, by means of carbolic injections, as recommended by Raimbert. He, however, used a stronger solution than one of 2 per cent., as employed by Raimbert, varying it from 4 to 5 per cent. according to the degree of pyrexia and the gravity of the case. The same lotion was also applied to the pustule externally.

FOREIGN UNIVERSITY INTELLIGENCE.

Dorpat.—Dr. C. H. Löhlein, *privat-docent* in midwifery, is to be offered the chair of Midwifery, Gynæcology, and Diseases of Children, which will become vacant by the transference of Professor Runge to Gottingen.

Gottingen.—Dr. H. Schwartz, Professor of Midwifery and Gynæcology, is about to retire at the end of the current winter session. Professor Runge of Dorpat has been invited to accept the chair, and has consented to do so.

Innsbruck.—Dr. Kratter of Graz has been appointed Professor of Medical Jurisprudence.

MR. JONATHAN HUTCHINSON has promised to read an address at the annual meeting of the Cardiff Medical Society in January next.

WE have just received the report of the medical officer of the Local Government Board for the year 1886, being the supplement to the sixteenth annual report of the Local Government Board. It contains matter of exceptional interest. Among others, in addition to the medical officer's own report, are papers on the Statistics of Small-pox Incidence upon the Registration Districts of London relatively to the Operations of the Small-pox Hospitals in the Metropolis, by Mr. W. H. Power; a report by Dr. Klein on the Etiology of Scarlet Fever; a further paper on the Etiology and Pathology of Tuberculosis, by the same author and Mr. Lingard; and the results of investigations into the Causation of Diphtheria, by Dr. Greaswell, Dr. Turner, and Mr. Power. We propose to discuss these subjects at length in future numbers.

THE death is announced of Mr. James Stephens, F.R.C.S., a well-known Manchester surgeon, which took place on the 1st inst. at his residence, Bridge-street, in that city, where he had lived for upwards of seventy years. With the exception of Mr. John Boutflower, he was the oldest medical practitioner in Manchester, having succeeded to the practice of his uncle, the late Mr. Joseph Jordan, founder of the Manchester Medical School.

WE regret to announce the death on the 2nd inst. of Sir William Richard Edwin Smart, K.C.B., M.D., Inspector General of Hospitals and Fleets (retired), after a short illness, at the age of seventy. The deceased joined the naval medical service in 1841, and retired from it in 1877. We hope in our next issue to publish a more detailed account of Sir William s career.

THE Minutes of the recent session of the General Medical Council, with the revised Standing Orders of the Council appended, has been published, and may be obtained, price 3*s.* 6*d.*, by those interested in them.

UNIVERSITY OF LONDON.

THE following statement has been sent in to the Privy Council:—

University of London, W., 1887.

SIR,—I am directed by the Senate of the University to avail myself of the permission given by your letters of the 1st and 15th July, and to lay before my Lords of the Council the following statement on the petition of University and King's Colleges, London, praying for a University Charter:—

The intimate relation which has long subsisted between this University and these Colleges, and the important consequences which may follow in the event of their petition receiving Royal favour, have occupied the anxious attention of the Senate; and they believe that they would be greatly wanting in their duty to the institution placed under their guidance if they did not call to these subjects the attention of the Lords of the Council.

This University and University College, London, were first incorporated by Charters bearing the same date (Nov. 28th, 1836); and these Charters were beyond question parts of one plan, in which the duty of giving teaching of a University character was assigned to the College, and the duty of examining to the University. King's College, which had previously been constituted by Royal Charter, was also affiliated to the University. The affiliation of Colleges subsequently lost its importance, owing to the fact that by the provisions of the new Charter of 1858 attendance at an affiliated College was no longer required, and that the examination rooms of the University were thus thrown open to students wherever educated. University College has, nevertheless, remained in close relationship with the University, and has supplied many of the most distinguished graduates and examiners to the University, and many of its members have been and are members of the Senate; above all the curriculum of instruction in the College has generally followed the lines of the examinations in this University. The connexion between the two institutions has thus been of great value to the University; and the Senate believe that by placing before the College a wide curriculum and a high standard of excellence they have also conduced to the very high position to which the College has attained.

The same observations apply to King's College; but in a lesser degree, inasmuch as the course of that College has been more influenced by the older Universities.

The Senate believe that a serious injury would be done to higher education if these two great London Colleges were to be entirely separated from this University, and were to adapt their courses of teaching, not to the examinations of this University, but to those of a new University in which the authorities of those two Colleges would exercise a dominant influence.

If the precedent which was set, or is supposed to have been set, by the

Digitized by Google

grant of the Charter to the Victoria University were followed by the creation of a second University in London, the Senate believe that Her Majesty's Government would find it difficult from time to time to resist similar applications from other Colleges in the country. The Senate fear that the creation of numerous small Universities would be fraught with danger to the cause of the higher education, and that the competition of graduating bodies would probably, if not at once, yet in no very remote future, lower the standard of graduation in a way of which the history of Universities contains numerous examples.

The Senate believe that the work done by the University has been and is of the greatest value to education, not only amongst their own graduates, but even in the older Universities. The width of the subjects embraced, the thoroughness of the examinations, and, above all, the independence of the examiners from all undue influence of the teachers, have had a widespread effect; and the Senate would greatly regret if the extent of this good work were lessened in the future by the withdrawal of a large number of the students of the most eminent Colleges from the examination rooms of this University to those of smaller Universities, where the granting of degrees would be practically in the hands of the teachers, and where the evils which the system of this University has checked would be sure to reappear.

So far as the petition of the Colleges complains of the want of regular communication between the University and the teachers of the higher institutions, the Senate do not desire to call it in question. On the contrary, from a date long prior to the presentation of the petition, or any proposal to present such a petition, both the Senate and the Convocation of this University have been engaged on the consideration of a plan for giving to the professors in the institutions from which graduates proceed an organisation and a larger influence in the counsels of the University. The general approval both of the Senate and of the Convocation has been given to this principle, and both bodies are, as the Senate believe, in substantial accord on the point, though the matter has not yet sufficiently ripened to admit of the presentation to Her Majesty of a joint petition for a Charter to give effect to the plan.

The scheme, which has been generally approved by the Senate, but is still subject to further consideration, proposes to unite into a class, under the name of Associated Colleges, educational bodies, not only in the metropolis, but throughout the country, which from the age of the students, the character of instruction given, and the fact that the Colleges have sent students as candidates for degrees in the University, may be worthy of association with it. It also proposes that the professors of these Associated Colleges, or representatives of the professors, should be gathered together into four groups or Faculties, according as they are concerned with arts, with laws, with science, or with medicine; and each Faculty is to select a smaller body to constitute a Board of Studies, which should aid the Senate and their committees in reference to the subjects of its Faculty. The examiners of the University, or some of them, are to be *ex-officio* members of the Boards of Studies.

The motives of these suggested changes are not far to seek. It was hoped that by giving to the teachers in the Associated Colleges a direct influence on the course of the examinations and a part in the government of the University two advantages would accrue. It would, to use a modern phrase, bring the Senate into touch with the actual teachers, and thereby remove any sense of dissatisfaction which may have been felt on their part, and any difficulty which may now exist in keeping pace with the varying requirements of the higher education; and, secondly, it would, it was hoped, awaken in the teachers of the several Colleges a sentiment of interest in the University which is now too often wanting, and which if created would strengthen its hands.

Furthermore, the Senate believe that such a union of the professors would be very beneficial to the Colleges which they represented, and that the closer connexion between the University and the Colleges would conduce to the benefit of the latter as well as of the former.

The Senate trust that before any radical change is effected in the organisation of the higher education in London the effect of such a scheme as has been sketched in outline will be fully considered by Her Majesty's advisers. The Senate believe that the result of such a scheme would be to unite together in organic relation the teachers of many of the principal Colleges throughout England and Wales, and that the London teachers, by their numbers, their eminence, and their nearness to the seat of the University, would exercise a great influence in its Faculties and Boards of Studies. In this way the Senate believe that the University would still further realise Her Gracious Majesty's opinion, recently expressed, that "it is a body which is eminently qualified to promote the advance of learning throughout her realm." The prospect presented by the alternative scheme now put forward by the Colleges is, the Senate believe, far less hopeful for the interest of education. A number, probably an ever-increasing number, of small universities removed from the beneficial and controlling influence of a great institution like this University, would come to compete for students and graduates with more regard to their number than to the character of their studies, and, if ever the present zeal for education should flag, would probably relaps into that condition of inefficiency into which even the great Universities of this country have at times fallen.

If the scheme for a modification of this University, to which reference has already been made, be carried into effect, the examinations of this University will be conducted as at present by entirely independent examiners, but the teachers will have a means of regularly communicating to the Senate their complaints, their wishes, and their views. If the petition of the Colleges be granted, a University will be constituted in which the whole power of conferring degrees will be in the hands of the teachers themselves.

The desire of many members of the Royal College of Physicians of London and of the Royal College of Surgeons of England to obtain for these bodies or for a body under their control the power of granting medical degrees has been a matter of notoriety for some time past. Though serious objections may be urged to such plan, it would be premature for the Senate to offer any observations upon a scheme which has not yet been put forward; and they only refer to it now as one of the elements of which account must be taken before the present demand of University and King's Colleges can be properly considered.

For this and many other reasons the Senate believe that the petition of University and King's Colleges cannot rightly be regarded as an isolated subject; but should be viewed in connexion, on the one hand, with the past history and future prospects of this University, and on the other hand, with reference to the very complicated conditions of the higher education in London. The Senate are at one with the petitioners in holding that the various teaching bodies in London would greatly gain by union and co-ordination; but they believe that this would be far more satisfactorily obtained under the supervision of such a body as this University than by the establishment of smaller and less responsible graduating bodies. If Her Majesty should think right to inquire into the working of this University, and into the condition generally of the higher education in London, the Senate of this University will do all in their power to assist in the solution of the complicated questions which would undoubtedly arise, and to make fruitful the results of the investigation.

The Senate has no desire to offer to the petition of the Colleges any selfish or captious opposition; but in the belief that issues of far-reaching importance are involved in the prayer of that petition, they desire the opportunity of showing cause before their Lordships why the prayer should not be granted

I am, Sir, your obedient servant,
ARTHUR MILMAN, Registrar.

THE ASSOCIATION OF GENERAL PRACTITIONERS AND THE PROPOSED DEGREE FOR LONDON STUDENTS.

THE following petition has been forwarded to the Privy Council by the Association of General Practitioners:—

To Charles Lennox Peel, Esq., C.B., Clerk to the Privy Council.

SIR,—We have the honour to ask you to lay before the Lord President and the members of the Privy Council an earnest protest on behalf of the Association of General Practitioners against some of the provisions of the Draft Charter for which the Councils of the Royal College of Physicians and the Royal College of Surgeons of England have petitioned. With the general object of obtaining for the students of the English medical schools and hospitals who pass their examination before the licensing bodies of London facilities for obtaining a degree which shall carry with it the title of "Doctor," the Association of General Practitioners is in entire accord. There is unquestionably a great hardship at present upon the licentiates of the London medical examining bodies, who, although possessing a curriculum equivalent to that of many of the British universities which confer medical degrees, have nevertheless no other facilities for acquiring such a degree than those afforded by the Universities of London. The standard of the University of London is expressly placed so high as to make it unattainable for more than a small minority of the London students. It is a degree of *élite*, and placed at so high a standard as to be altogether beyond the ordinary possibilities of the average student, even when thoroughly educated and carefully examined for all the necessities of general practice. In this respect, therefore, the English students are under a great disadvantage as compared with those especially of Ireland and Scotland, and this disadvantage is practically felt because, on the one hand, large numbers of students are thus attracted to the universities of Scotland and Ireland, where they obtain on reasonable conditions the title of M.D.; and, on the other hand, because Irish and Scotch students, who have received their degrees after an examination in no way more difficult than the average examination at present carried on in London by the examining bodies, settle in England, and practise alongside the London licentiates, with the added prestige of the degree and title of M.D., and thus claim a superior social and university status.

While, therefore, heartily concurring in and supporting the petition of the Colleges in principle for facilities for the licentiates of the London examining bodies to obtain the title of "Doctor of Medicine" under reasonable conditions, the Associaton of Practitioners earnestly protests against the attempt which is manifest in the petition of the two Royal Colleges to secure for themselves alone, and for their licentiates alone, a monopoly for such degrees which would operate most unjustly and injuriously to the interests of the public and of the profession in respect to the total exclusion from the further examinations which the Royal Colleges ask to be allowed to institute for the title of M.D. of all those members of the profession who for excellent reasons prefer the licence of the Society of Apothecaries. It must be remembered that the Society of Apothecaries, under the recent Medical Act, applied to the Royal Colleges of Physicians and Surgeons to be included in the combination which these two Colleges have formed for giving licences in Surgery, Medicine, and Obstetrics. A constituency of the Royal College of Surgeons assembled in annual meeting earnestly called upon the College to take that application into consideration, and it is a matter of universal knowledge that the whole voice of the profession was in favour of such a course. It should be remembered also that at an earlier date the two Colleges had, in conference with the Apothecaries' Society, settled a scheme for a conjoint board of examination, by which such combination of these three bodies, and of other examining bodies in England, would have been effected; and after such negotiations had been carried to that point, the Apothecaries' Society, at the instance and with the approval of the two Royal Colleges, applied to Parliament for a special Act, which was accordingly passed, to enable them to take part in such combination. Nevertheless, the Councils of the two said Colleges, who are two small and irresponsible bodies wholly composed of the class of consulting physicians and surgeons, resolved to exclude the Apothecaries' Society from any such combination. The General Medical Council of Education and Registration, after considering the subject, passed resolutions and made representations to the said two Colleges to induce them to alter this most unjust decision, as being contrary to the interests alike of the public and of the profession; but the two Councils once more abruptly declined.

Under these circumstances the Apothecaries' Society completely remodelled their examinations, the General Medical Council appointed its own examiners to supervise and complete the examinations of the Society in all departments, and such examinations are now carried on under the direct supervision and with the assistance of examiners directly appointed by the General Medical Council, in such manner as to afford a complete examination in all the departments of Medicine, Surgery, and Obstetrics.

The Royal Colleges are now asking the Privy Council to do by a side wind that which it directly refused to do in the framing of the Medical

Digitized by Google

Act, and that which the General Medical Council, following the voice of the great mass of the profession, also refused to do—namely, to treat the Apothecaries' Society with such injustice as effectually to exclude their licentiates from their just rights and privileges, and, in fact, to destroy the efficiency of the Society as an examining body.

The medical students who present themselves at the close of their career for examination at the Society of Apothecaries, and who become its licentiates, undergo a like preliminary examination with the licentiates of the two Royal Colleges, and such preliminary examination must have the like approval of the same authority—the General Medical Council—in order that they may all be entered on the "Register of Medical Students," which is kept by the General Medical Council. The conditions as to age and preliminary education are the same; the curriculum of education is the same; they are educated during the same number of years, in the same schools, the same hospitals, and by the same lecturers as those who take up the licence of the Royal College of Physicians and the Royal College of Surgeons. The examinations are conducted by Fellows and Members of the said Colleges, and with the aid of the Fellows and Members of the Society of Apothecaries, and of examiners specially appointed by the General Medical Council. They must, therefore, all alike fulfil the now fully adequate State requirements of a uniform minimum qualification.

The Association of General Practitioners ask, therefore, that the serious, inequitable, and unjust action shall not be perpetrated of excluding these gentlemen, similarly educated, similarly examined, and equally qualified, from any further examination for the degree and title of "M.D." in London, such as that for which the petition is now before the Privy Council. They earnestly and respectfully pray that in any Charter which may be granted for that purpose clauses shall be inserted that shall give to the licentiates of the Society of Apothecaries in Medicine and Surgery the same right to present themselves for examination, and if found duly qualified, to receive the title and degree of M.D. as the Royal Colleges ask for their licentiates. It should be noted that in neither case is any further educational curriculum to be imposed, and the only application of the two Colleges is for permission to create a further examination for the new degree. It is submitted that to exclude the licentiates of the Society of Apothecaries, who have passed through the same curriculum with the same teachers for the same time and at the same place as those whom the Royal Colleges propose to examine, would be a totally indefensible attempt to create a special monopoly for these two Colleges for their own benefit alone, and one altogether contrary to public right, public justice, and public interests. The Association of General Practitioners it is proposed to establish, and which it is proposed to call a Senate, is one altogether contrary to the general principles of constitution of such bodies which ought not to be permitted. Under the Draft Charter which is now submitted to the Privy Council it is proposed that the governing body shall be composed of the Councils of the College of Physicians and the College of Surgeons. Now, the Council of the College of Physicians is composed of an entirely self-elected and irresponsible body of members, wholly composed of the class known as consulting physicians, and in this body even the provincial consulting physicians are very slightly represented. The Council of the College of Surgeons is also a body representative only of a very small minority of the great body of licentiates of the College, the members, numbering 15,000, being wholly excluded. In the new governing which it is proposed to set up, these two inadequately constituted and unrepresentative Councils propose to assume to themselves the whole management of the University.

The general practitioners of England are at present totally debarred from representation on the Council of the College of Physicians, and practically debarred from representation on the Council of the Royal College of Surgeons, and it would be most unjust and altogether contrary to precedent that they should, as is now proposed, be also debarred from any representation on the new Senate, which is avowedly created for the express and sole purpose of granting adequate degrees to general practitioners. For the class of consulting physicians and surgeons, of whom the existing Councils are made up, and of whom the new Senate, according to the Draft Charter, would be made up, are fully provided with adequate facilities for graduating at the Universities of London, Oxford, and Cambridge, and the new Charter and new Senate are avowedly asked for with the sole purpose of creating facilities for graduation in medicine for general practitioners. Nevertheless it is proposed that the whole vicious constitution shall be maintained, and that general practitioners, for whom alone this new Senate or University is to be created, shall be wholly debarred from any share in its government or representation on its Council. The new graduates, however capable, however eminent, will in no way be represented. Once given their degrees, they cease to have any voice or vote in the management of the University of which they are graduates. Even if the Councils out of which it is proposed to elect the Senate were more satisfactorily constituted, it would be totally inadequate and unsatisfactory in constitution, but it is especially so considering the extremely unsatisfactory character and constitution of those bodies.

In this respect, also, your petitioners pray that the Privy Council will not allow a constitution of the governing body which is unknown to any other University throughout the kingdom, and which is totally out of accordance with any of the principles on which such governing bodies when created are now constituted. The Council will be prepared to support these arguments and this prayer by deputation, if the Privy Council think fit to receive such deputation, or by any other method indicated. They earnestly pray that the Lords of the Privy Council will not accede to an application containing so many elements of injustice and so contrary to public policy, public interest, and the general feeling of the whole body of the profession, without taking steps to carefully ascertain what is the opinion of the profession on the subject, and without giving effect to the general principles of public right.

It should be mentioned that the two said Councils, of which the constitution has been above referred to, have not in any way submitted this Charter to the large body of their members and licentiates, but have discussed the same in secret councils, and have forwarded it to the Privy Council without submitting it to the professional opinion which they have reason to know would wholly condemn the clauses to which reference is made above.

We have the honour to be, &c.,

C. G. WHEELHOUSE, President.
H. WALTER VERDON, } Hon. Secs.
W. GIBSON BOTT, } Association of General Practitioners.

419, Brixton-road, S.W.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN twenty-eight of the largest English towns 5737 births and 3978 deaths were registered during the week ending December 3rd. The annual rate of mortality in these towns, which had been 20·0, 21·1, and 23·5 per 1000 in the preceding three weeks, declined again last week to 22·5. During the first nine weeks of the current quarter the death-rate in these towns averaged 20·6 per 1000, and was 0·7 below the mean rate in the corresponding periods of the ten years 1877-86. The lowest rates in these towns last week were 15·5 in Brighton, 16·2 in Hull, 16·3 in Norwich, and 17·3 in Sunderland. The rates in the other towns ranged upwards to 29·6 in Oldham, 30·4 in Blackburn, 31·1 in Bolton, and 35·6 in Newcastle-upon-Tyne. The deaths referred to the principal zymotic diseases in the twenty-eight towns, which had been 404 and 480 in the preceding two weeks, declined again last week to 443; they included 108 from scarlet fever, 96 from whooping-cough, 69 from measles, 59 from "fever" (principally enteric), 48 from diphtheria, 37 from diarrhœa, and 26 from small-pox. No deaths from any of these zymotic diseases were registered last week in Cardiff, whereas they caused the highest death-rates in Derby, Salford, and Sheffield. The greatest mortality from scarlet fever occurred in Sheffield, Norwich, Bristol, Bradford, Birkenhead, and Salford; from measles in Birmingham, Oldham, Bradford, Nottingham, Blackburn, and Derby; from whooping-cough in Newcastle-upon-Tyne; and from "fever" in Preston. The 48 deaths from diphtheria in the twenty-eight towns included 28 in London, 4 in Birmingham, 3 in Sheffield, and 2 in Portsmouth, in Huddersfield, and in Newcastle-upon-Tyne. Small-pox caused 25 deaths in Sheffield and 1 in Bristol, but not one in London or in any of the twenty-five other large provincial towns. The metropolitan hospitals receiving cases of small-pox contained 12 patients on Saturday last, against 16 and 13 on the preceding two Saturdays. The number of cases of scarlet fever in the Metropolitan Asylums Board hospitals and in the London Fever Hospital at the end of the week was 2726, against 2764 on the previous Saturday; the cases admitted showed a decline from the number in the previous week. The deaths referred to diseases of the respiratory organs in London, which had been 438, 461, and 560 in the preceding three weeks, declined again last week to 455, and was 27 below the corrected average. The causes of 89, or 2·2 per cent., of the 3978 deaths in the twenty-eight towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Portsmouth, Nottingham, Bolton, and in three other smaller towns. The largest proportions of uncertified deaths were recorded in Huddersfield, Halifax, Salford, and Sunderland.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 19·9, 22·0, and 23·5 per 1000 in the preceding three weeks, further rose to 25·0 in the week ending Dec. 3rd; this rate exceeded by 2·5 the mean rate during the same week in the twenty-eight large English towns. The rates in the Scotch towns last week ranged from 17·1 in Greenock and 21·9 in Edinburgh, to 30·8 and 37·6 in Perth and Paisley. The 624 deaths in the eight towns last week showed a further increase of 44 upon the numbers returned in recent weeks, and included 28 which were referred to whooping-cough, 13 to scarlet fever, 12 to measles, 10 to diarrhœa, 9 to "fever" (typhus, enteric, or simple), 5 to diphtheria, and not one to small-pox; in all, 77 deaths resulted from these principal zymotic diseases, against 74 and 78 in the preceding two weeks. These 77 deaths were equal to an annual rate of 3·1 per 1000, which exceeded by 0·6 the mean rate last week from the same diseases in the twenty-eight English towns. The fatal cases of whooping-cough, which had been 26 and 30 in the preceding two weeks, were last week 28, of which 14 occurred in Glasgow and 3 in Dundee. The 12 deaths from measles were within one of the number in the previous week, and included 7 in Dundee and 3 in Edinburgh. The fatal cases of scarlet fever, which had been 16 and 11 in the previous two weeks, rose again last week to 13, of which 8 occurred in Glasgow and 3 in Dundee. The 10 deaths attributed to diarrhœa somewhat exceeded the low numbers in recent weeks. The 9 deaths

Digitized by Google

from "fever," on the other hand, showed a decline, and included 4 in Paisley, 2 in Glasgow, and 2 in Edinburgh. Four of the 5 deaths from diphtheria were returned in Glasgow. The deaths referred to acute diseases of the respiratory organs in the eight towns, which had been 107, 144, and 156 in the preceding three weeks, further rose last week to 165, and were 23 above the number returned in the corresponding week of last year. The causes of 81, or nearly 13 per cent., of the deaths registered in the eight towns during the week were not certified.

HEALTH OF DUBLIN.

The rate of mortality in Dublin, which had been 34·6 and 33·8 per 1000 in the preceding three weeks, further rose to 35·0 in the week ending December 3rd. During the first nine weeks of the current quarter the death-rate in the city averaged 30·5 per 1000, the mean rate during the same period being but 19·8 in London and 19·5 in Edinburgh. The 237 deaths in Dublin last week showed an increase of 8 upon the number returned in the previous week; they included 13 which resulted from scarlet fever, 8 from measles, 4 from whooping-cough, 3 from "fever" (typhus, enteric, or simple), 2 from diarrhœa, 1 from diphtheria, and not one from small-pox. Thus the deaths resulting from these principal zymotic diseases, which had been 45, 29, and 33 in the preceding three weeks, were 31 last week; they were equal to an annual rate of 4·6 per 1000, the rate from the same diseases being 2·6 in London and 2·0 in Edinburgh. The fatal cases of scarlet fever, which had been 20, 8, and 11 in the previous three weeks, rose again last week to 13, while those of whooping-cough showed a decline. The deaths referred to measles, "fever," and diarrhœa corresponded with the numbers in the previous week. The deaths of infants corresponded with the number in the previous week, while those of elderly persons showed a further increase upon recent weekly numbers. Seven inquest cases and 5 deaths from violence were registered within the city; and 65, or more than a fourth, of the deaths occurred in public institutions. The causes of 36, or more than 15 per cent., of the deaths in the week were not certified.

FRENCH URBAN MORTALITY STATISTICS.

Since the beginning of the present year an official monthly return has been issued by the Bureau de l'Hygiène Publique in Paris, entitled "Statistique Sanitaire des Villes de France et d'Algérie." This return is a most valuable and welcome contribution to the various official returns dealing with the vital statistics of European cities, and gives, with considerable detail, the statistics of all French cities having a population of 30,000 persons and upwards. It is not without interest to note from this return that France contains fifty-one towns, with populations exceeding this limit, and that the aggregate population of these fifty-one towns slightly exceeds six and a quarter millions. In England and Wales at the last census enumeration in 1881, there were forty-seven towns with a population exceeding 50,000 persons, and containing an aggregate population of nine and a half millions. Therefore at the time of the last census considerably more than a third of the population of England and Wales resided in forty-seven towns having a population exceeding 50,000 persons; whereas in France only one-sixth of the population resides in thirty towns of the same minimum population. Even these figures only imperfectly indicate the marked excess of urban population in England and Wales; for while England has twenty-two towns having a population exceeding 100,000, France has only eleven towns exceeding this limit. In any comparison of the mortality statistics of the two countries, it is necessary to take full account of this wide difference between their proportions of urban population. The new French return, valuable as it is, and abundant as is the statistical material it contains, has one marked defect: no totals are given for the aggregate of the towns, and, moreover, only the bare facts are given, without any calculated proportions to population, which are necessary to make the figures intelligible and useful for comparative purposes. Having incurred the labour of casting the facts for the aggregate of the fifty-one French towns, it appears that the mean annual death-rate was equal to 26·1 per 1000 in August and to 21·4 in September, or to 23·8 in the two months. In the twenty-eight English towns (having a minimum population of nearly 80,000, instead of 30,000 as in the French towns) the annual rate during the months of August and September last did not exceed 20·0 per 1000. Thus in the smaller French towns the mortality during these two months showed an excess of 19 per cent. upon that which prevailed in the English towns. It is noteworthy that of the four largest French cities—Paris, Lyons, Marseilles, and Bordeaux—Marseilles is the only one showing a rate (29·1) exceeding the mean rate in the fifty-one towns, while the mean rate in these four largest cities did not exceed 21·7, against 23·8, the mean rate in the fifty-one towns. It is evident, therefore, that the largest excess of mortality in the French towns during August and September last occurred in the smaller towns.

THE SERVICES.

WAR OFFICE.—Army Medical Staff: Surgeon Samuel Arthur Crick, M.B., has been placed upon temporary half-pay on account of ill-health (dated Nov. 27th, 1887).

VOLUNTEER MEDICAL ASSOCIATION.—Ambulance Department: The appointment of Acting Surgeon Walter Pearce, M.D., as Instructor to the Ambulance Department of the Volunteer Medical Association, has been cancelled.

Correspondence.

"Audi alteram partem."

SUPRA-PUBIC LITHOTOMY.

To the Editors of THE LANCET.

SIRS,—I am compelled to trouble you with a note relating to the history of supra-pubic lithotomy given by Dr. Dulles in your issue of last week. The reference which Dr. Dulles does me the honour to make is, however, not accurate, and I am sure he has no desire that it should remain so. It is in these words: "And lastly, the conversion of Sir Henry Thompson, who, after long denying its claims, has become one of its most enthusiastic propagandists."

There are two forms of the operation: the old one before Petersen made his modification, and that which has been employed since. I have never denied the claims of either. The old operation I had occasion to perform twice only—once in University College Hospital, and once in private. I always regarded it as a rare and occasional resource for very large calculi, seldom necessary, but certainly had no prejudice against it whatever. The new operation I advocated on the ground of reports respecting it which I had confidence in, even before I had tried it, at my lectures at the Royal College of Surgeons in June, 1884. I stated that Petersen's modification had given "a new and improved position to the high operation," adding that "in the next case for which the knife is required I shall perform the operation on his method." A week after such a case occurred, and I did so, and so introduced the proceeding into this country. I have followed it by twenty-four other cases since, selecting the most formidable cases for the purpose, and am as satisfied with it now as I was at the outset.—I am, Sirs, yours truly,

Wimpole-street, W., Dec. 6, 1887. HENRY THOMPSON.

THE COMPULSORY NOTIFICATION OF INFECTIOUS DISEASES.

To the Editors of THE LANCET.

SIRS,—Now that the question of compulsory notification of infectious diseases is prominent, it appears opportune to call attention to a Society which is quietly at work in the parishes of St. Margaret and St. John, Westminster. About five years ago Mrs. Johnson, at a meeting held at the house of Archdeacon Farrar, called attention to a Society she had started in Hastings for the notification and prompt discovery of infectious disease, and for dealing with the infected area on scientific principles. She advocated the extension of the system to the metropolis, and forthwith the Westminster Sanitary Aid Association was started in the joint parishes of St. Margaret and St. John. Now, I desire to call the attention of the medical profession

Digitized by Google

at large to the objects of this Association, and, further to observe that while in nearly every other part of London a serious epidemic of scarlet fever has been raging, in these two parishes, which contain a population of 60,000, the number of cases notified to the Society have barely exceeded the average of the last four years; and, as far as the above parishes are concerned, there has been really no epidemic of scarlet fever or other infectious disease.

In the last six months of 1886 thirty-three cases of infectious disease came under the notice of the Society's officers, and in the five months from June 29th up to date the number has been thirty-nine. Now, in the absence of all compulsory notification, these figures may appear to have little value; but really the success of the Society has been so great, and has so enlisted the sympathy and co-operation of the medical men resident in the district, that practically the notification of all infectious diseases is immediately communicated to the Society.

We have also the cordial co-operation of the medical officer of health and his sanitary officers, who inform us of every case that comes under their official cognisance; and in return we take immediate steps for disinfecting the infected house, removing in the meantime, if necessary, the healthy occupants to our sanitary house at 1, Edward-street, Vincent-square, while the process of disinfection is being carried out. This is done effectively by our nurse and indefatigable lady manager, Miss Stevenson, who seal up the infected house or dwelling room for at least twelve hours and burn sulphur cakes. All the bedding and clothing, of course, is opened and exposed to the fumes. As a matter of fact, in almost every case Miss Stevenson, by judicious reasoning and persuasion, induces the parents or friends to consent to the removal of the sufferer to the fever hospital, and I am happy to say that, mainly owing to the good work of this Society, the opposition to the Bill for the Compulsory Notification of Infectious Disease has practically died out amongst the tradesmen and shopkeepers in this district, so much so that last week the Sanitary Committee of the Westminster District Board of Works, on the invitation of the Medical Officers of Health Association and the vestry of Kensington, decided to petition the Government to bring in this Bill. It appears certain that in the next Parliamentary session this question will be effectually dealt with, and I cannot but feel proud that in this district we have, so to speak, inserted the thin edge of the wedge, and taken the first step in practically testing the machinery which must be set in motion when this Bill becomes law.

I am, Sirs, your obedient servant,

THOS. BOND, F.R.C.S.,
Member of the Sanitary Committee of the Westminster Board of Works.

The Sanctuary, Westminster, Nov. 28th, 1887.

*** The objects of the Westminster Sanitary Aid Association are to provide female sanitary visitors to teach the practice of disinfection, to promote the removal of infectious cases to hospital, to assist, when local circumstances permit, in the isolation of the sick in their own homes, and, further, to watch over houses in which infectious disease has recently appeared. The Association also aids in the nursing of the sick, in the prevention of attendance at school of children likely to convey infection, in procuring the sanitary improvement of houses in which are found conditions prejudicial to health, and, finally, in enlisting the co-operation of all existing sanitary agencies in the prevention of infectious disease.—ED. L.

SIR JAMES PAGET'S "MORTON LECTURE" ON CANCER AND CANCEROUS DISEASE.

To the Editors of THE LANCET.

SIRS,—In the discussion on Cancer at the Pathological Society in 1873 Sir James Paget stated that since his practice had become exclusively, or almost exclusively private, one in every three was the proportion of instances in which it was possible to discover a history of cancer in the family of his cancerous patients.

The report of the Collective Investigation Committee on Cancer of the Breast shows that 210 returns contained definite statements as to the heredity of cancer. Of these 116 were to the effect that there was no family history of cancer, while in 68 cancer had occurred in other members of the patient's family; the proportion is therefore more than one in three.[1]

From a large number of cases of cancer which I have collected in hospital and private practice, I find the proportion of cases with a family history of cancer is slightly below one in four cases, and in several cases several members in the same family were affected with the disease. Of two of the most striking cases, one was that of a man aged sixty-one, who died of cancer of the tongue, in which the lymphatic glands in the neck were extensively involved. His father died of cancer of the penis, aged sixty-three; his uncle (father's brother) died of cancer of the tongue, aged sixty-three; his father's sister died of cancer of the breast, aged sixty-five; his mother also died of cancer of the uterus. The other case was that of a gentleman who died of a malignant nasal growth; one sister died of cancer of the breast, and another of cancer of the stomach; these three died within a period of fourteen weeks.

The further experience of Sir James Paget evidently has not shaken his belief in the constitutional origin of cancer, or that it is a blood disease and probably of micro-parasitic origin. I have always contended, and the results of my investigation, so far as they have gone, support my contention, that to satisfactorily account for the occurrence of cancer in any individual two factors must be present: the one, as Sir James Paget describes it, general or diffused in a morbid material in the blood; the other local, in some part with which the material produces disease.

No surgeon doubts that the development of malignant disease is nearly always due to local irritation of the part affected; but to prove that the local irritation is the actual cause of the malignant growth, I submit that the same irritation existing in another individual of similar age &c. should produce the same result in the majority, if not in all, cases. This we know is not the fact. What explanation can we give, then, to account for the disease developing in one case and not in the other? I contend there can be but one reasonable explanation, and that is: in the one case the soil is adapted to the growth of cancer—i.e., that there is some morbid condition of the blood which renders the individual liable to the disease; while in the other case there is no such condition of the blood.

The case reported by Mr. Jennings in your last week's issue, in my opinion, illustrates this in a peculiar manner, as it is most rare to find cancer existing symmetrically as he has depicted in any one individual; and while the same cause of irritation might have caused the disease on either side of his patient's face, yet I doubt if such would have occurred had there not been some marked condition of the blood existing.

One word with regard to the treatment of cancer with Chian turpentine. I have given this drug an extensive trial in numerous cases of cancer of the breast, tongue, and uterus. Notwithstanding the patients took this drug on exactly the same lines as laid down by Mr. Clay, I have not seen the slightest good effect in any case of cancer of either the breast or tongue. In some of the cases of cancer of the uterus the patients have expressed themselves as free from pain, and the offensive smell has been lessened; but in no case have I seen the disease cured or otherwise improved. I hope, however, to report on the cases treated by me at the Cancer Hospital by this drug more fully at a future date.

I am, Sirs, yours faithfully,

F. BOWREMAN JESSETT, F.R.C.S. Eng.

Upper Wimpole-street, W.

THE TREATMENT OF CANCER.

To the Editors of THE LANCET.

SIRS,—In your issue of the 3rd inst., Dr. Elder of Nottingham, referring to the treatment of cancer by Chian turpentine, says that "seven years ago Professor Clay gave to the profession the welcome intelligence that at last a specific cure for cancer had been found in Chian turpentine." He proceeds to assert that "no remedy has had a fairer trial at the hands of his *confrères*, or [has] more grievously disappointed them." As a mere matter of justice I am bound to

[1] Vide Report, Brit. Med. Jour., vol. i., p. 37. 1887.

Digitized by Google

traverse these assertions. I did not declare the discovery a "specific cure" for cancer. I stated in my first communication to THE LANCET that, as the result of experiments carefully made and continued for a considerable time, I had found Chian turpentine beneficial in certain cases of cancer —uterine cases were those especially referred to—in a degree far greater than in the case of any other means then adopted. I said that as the result of using the drug, under the conditions I then specified, the progress of the disease had been arrested, hæmorrhage had ceased, pain had been alleviated, and the growth had finally disappeared. I supported these statements by details of cases, and upon them I based the conclusion that an agent had been discovered by which this terrible malady might be held in check in a manner hitherto unhoped for. In a later paper, I stated my belief, founded upon longer experience, that it was possible to formulate in certain cases a plan for the treatment of cancer which would result in a cure. This conclusion I again supported by the citation and description of cases. Still later, in your journal of the 19th of November of this year, I gave details of other cases which supported my view; and I have also received independent testimony from medical men who have tried the remedy or have watched its trial, and have acknowledged similar results.

To speak of the proclamation of a "specific cure" when the claim put forth was tentative and experimental, and was from time to time supported by the publication of cases open to inquiry, is nothing but an abuse of terms; and, in the presence of the evidence of benefit referred to, it is equally an abuse of terms to speak of the "almost unanimous condemnation" of the use of Chian turpentine in cancer. I have hundreds of letters from medical men and their patients testifying to the great benefit experienced from the treatment. As to the fair trial of the alleged resulting grievous disappointment, I have to say that it is useless to attempt to do what many of those who condemn the treatment have done—namely, to apply it without reference to the conditions which, according to my experience, are necessary to success. I have invariably declared that to be of value the treatment must be adopted in an early stage of the disease, that it must be persistently continued, and that it must be enforced with due regard to all the circumstances of particular cases. It is obviously unjust to the treatment to have recourse to it in advanced stages when, as some medical men have admitted, "the end is near," and then to expect beneficial effects which are obtainable only in conditions affording reasonable hope of advantage. Such an assumed trial is not a fair one, and any condemnation based upon it is valueless. In the face of such statements I must be pardoned if I prefer to adhere to the evidence of my own experience; and here I affirm that, referring especially to uterine cases, only twice out of numerous examples have I seen a cloaca develop when the drug has been properly used, both as to method and time. That, as shown by the Middlesex Hospital Reports, such patients have died from other causes I do not contest, and it is obvious that fatal results occur when the use of the Chian turpentine is complicated and hindered by the use of opium and its derivatives. I cannot too often or too strongly repeat that to give it full and fair effect the remedy must be employed under the conditions which alone in my experience render it operative. If medical men will resort to the remedy at an early period, will persist in its use under apparent difficulties, will avoid opiates, and will give increasing doses, I am convinced that the reported failures will be replaced by records of numerous and most gratifying successes; but if success is to be obtained, the conditions essential to progress must be observed. With reference to your own observations on the subject, I have to thank you for their courteous and considerate tone, prompted by a manifest desire only to arrive at the truth. That is my own desire. I shrink from no test of the cases I have recorded, and from no method of inquiry based upon sound principles and controlled by adequate conditions. I should welcome such an inquiry, but it is obvious that the claims of a large private practice and detachment from hospital work prevent me from conducting investigations such as those by M. Pasteur with regard to hydrophobia. I can only continue my own investigations as cases occur in my practice. These, by their results, confirm my original conclusions in an increasing degree, and I shall, as they progress, be willing to communicate to the profession both the results and the details of the cases upon which they are established. If others will, under the same conditions, adopt the course I have recommended, I do not doubt that their conclusions will confirm my own.

I am, Sirs, yours faithfully,

Birmingham, Dec. 6th, 1887. JOHN CLAY.

To the Editors of THE LANCET.

SIRS,—Mr. Jennings, in your last number, commenting on Sir James Paget's "Morton Lecture," says: "Instances in which the disease [cancer] has been cured are familiar to most practitioners." As I read Sir James Paget's conclusion, it is that in his vast experience he has never yet met an instance of cure. During forty years, in an almost unlimited field for observation, it has never been my lot to see one. If Mr. Jennings or Mr. Clay will lay before the profession a solitary instance in which any cancer infiltrating the textures immediately around its origin, or contamination of the adjacent glands, has been cured by any mode of treatment—not excepting the use of the knife—a result will have been attained not hitherto acknowledged by pathologists. At present I am unable to regard the cases referred to and published by either of these gentlemen as being instances of cancer.

To Mr. Clay an appeal has been made both by Mr. Lawson Tait and myself, as the following extracts will prove:—

"Let him, Professor Clay, submit his cases to his colleagues or other competent observers, that the actual existence of cancer may be beyond dispute; let him cure a single case, and he will have no reason to complain of the congratulations he will receive from the profession in Birmingham or elsewhere."[1]

"I attended at the Queen's Hospital, at Professor Clay's request, and was shown by him three or four cases of undoubted cancer in the breast in various stages of progress, and all of which were being treated by Chian turpentine. I was to see them again in six weeks, and the time having expired I wrote to Professor Clay on the subject. I have his letter by me, dated Feb. 1884, in which he tells me the cases were otherwise ill, and not to be seen, save by possible postponement; and this is all I have been able to gather of Professor Clay's treatment by Chian turpentine of his own cases, submitted for inspection."[2]

Surely there is no time like the present for the "careful re-examination of all the evidence Mr. Clay can produce." These are your editorial words in considering his recent cases. Other correspondents ask for a "tribunal" of inquiry,[3] whose judgment the profession would recognise. It cannot, I venture to think, be a moment too soon to arrest the further administration of a nauseous drug in cases already pronounced hopeless, or to promote its administration by every means in our power.

I am, Sirs, yours faithfully,

Birmingham, Dec. 6th, 1887. OLIVER PEMBERTON.

To the Editors of THE LANCET.

SIRS,—I agree with Mr. George Elder's letter in your last issue, that the claims Mr. Clay makes for Chian turpentine ought not to pass unchallenged by those who differ from him. I have tried the treatment in six cases of uterine cancer and three of cancer of the tongue, and am giving it one more trial at the present time in cancer of the tongue and throat, but as yet I have not seen the slightest benefit derived from the treatment. I am, Sirs, yours truly,

Torquay, Dec. 1887. W. T. BOREHAM, M.D.

THE DIPLOMA IN PUBLIC HEALTH OF THE APOTHECARIES' SOCIETY OF LONDON.

To the Editors of THE LANCET.

SIRS,—As being directly and mainly responsible for the wording of Section 21 of the Medical Act, 1886, which deals exclusively with the registration of diplomas in sanitary science, I would like to state that it was never intended that the Apothecaries' Society and Hall should be permitted to participate in having their diplomas in public health registered—i.e., if these bodies in the future desired to grant such,—and the wildest interpretation of the said section cannot be made to include these bodies; therefore I, for one,

[1] THE LANCET, Oct. 23rd, 1880. Letter from Mr. Tait.

[3] Mr. Elder's letter, THE LANCET, Dec. 3rd.

Digitized by Google

am pleased that the General Medical Council has referred the matter for the opinion of counsel at the instance of Dr. Heron Watson. On the notice paper of the House of Commons, May 17th, 1886, both Sir Henry Holland and Sir Lyon Playfair placed amendments to the Medical Act (1858) Amendment Bill. Sir Henry Holland's clause included "universities or medical corporations of the United Kingdom," which would have, if passed, included the Apothecaries' Society and excluded the Colleges of Surgeons, while the Government clause simply mentioned "any university in the United Kingdom," and excluded all the Colleges and Apothecaries' Societies. Sir Henry Holland's clause was dropped as an amendment, and on my writing to Sir Lyon Playfair to include the various Colleges in the matter of registration, I was informed, in a letter dated May 26th, 1887, that Sir Lyon Playfair had done so; and also by reference to Section 21 my other suggestions were carried out. The section reads—"a diploma, granted by any College or Faculty of Physicians or Surgeons or University in the United Kingdom, or by any such bodies acting in combination, &c." Surely no one can interpret that either of the Apothecaries' Societies is included in this section, and is entitled to registration.

I am, Sirs, yours faithfully,

J. EDWIN COONEY, D.P.H.Camb.,
Late Hon. Sec. Public Health Medical Society.

Vereker-road, West Kensington, S.W., Nov. 26th, 1887.

TREATMENT OF ECZEMA AND PSORIASIS.

To the Editors of THE LANCET.

SIRS,—In Dr. Myrtle's interesting account of his successful treatment of eczema and psoriasis by means of the Harrogate sulphur waters, he relates the case of a surgeon who, when he was approximately well, after reading a paper of mine on Counter-irritation over the Vaso-motor Centres in Obstinately Recurrent Eczema, applied a mustard plaster to his nape, and the eczema was set going again. Now, it is a well-known fact that doctors seldom treat themselves judiciously, and in medicine, as in the affairs of this life generally, it is always best to "let sleeping dogs lie." Dr. Myrtle, however, takes occasion from this case to remark: "With all deference to Dr. Crocker, and whilst concurring in his views as to the influence the vaso-motors have in eczema, I cannot speak too strongly against the application of counter-irritants to the skin of the eczematous for any purpose whatever."

Lawyers have a well-known dictum, that "single cases make bad law," and the same statement holds good for physic. If I were to relate the case of a patient whose eczema had been aggravated by the injudicious use of the Harrogate waters (not a difficult thing to do), and upon that said, "With all deference to Dr. Myrtle, the Harrogate waters should not be used in eczema on any pretext whatever," he would, I think, not only perceive that "all deference" was curiously shown in a flat contradiction of his statements, but also point out that numerous and striking successes showed the utter fallacy of such sweeping statements. The fact is, that every remedy which is worth anything is potent for evil as well as good, and that when a new treatment is being tried the views of the originator as to the selection of the case and the mode of carrying out the treatment should be strictly observed, at all events until the practitioner has some experience of the weapon he is wielding; disappointment is otherwise pretty sure to be the result, and perhaps a valuable aid discredited. Further experience in the employment of counter-irritation over the vaso-motor centre of the affected region in obstinately recurrent eczema has only confirmed and extended my first statements. It should be used when the fresh attack is impending, of which the patient generally has a few hours' notice by his sensations. The attack may thus often be either warded off or greatly mitigated, as many of my cases prove, and other observers can corroborate by independent testimony. The treatment, however, should never be applied when the activity of the eruption is abating, as the last case in my original paper demonstrated. Great relief may also often be obtained where severe paroxysms of itching render the patient's life a misery, as in the following case:—A tall, strong man, aged thirty-eight, came to the hospital with eczema of the scrotum and inside of the thighs of three months' duration. The irritation became so great that even when showing his disease he could not refrain in the presence of all the students from scratching most frantically. A mustard leaf was ordered over the lower dorsal and upper lumbar spines, but he put it on too low down, and only experienced slight relief; another was ordered higher up, and the next note was, "Irritation is much less to-day." A week later a fresh attack with "frightful itching" was coming on, and the mustard was reapplied. It gave him immediate relief for twelve hours, and then there was a slight return of itching for a few hours; after this the eruption and irritation got better, and had continued to do so until his next visit. The treatment had to be repeated twice more before the tendency to recurrence was quite subdued, but after that he got so well that he ceased to attend three weeks from the commencement of the mustard treatment. In another case a man aged fifty-one had acute eczema of the face, arms, and forearms, which were streaming with serous exudation, attended with much itching and burning. He improved at first with topical applications and saline aperients, and then a fresh attack ensued. A mustard leaf was applied over the nape; he felt great relief to the head; the irritation was better next day. The discharge from the face three days later being very great, mustard was reapplied. This stopped the exudation from the face at once, but not from the arms, which ceased gradually; and from that time the case gave no further trouble and required no more mustard, though he was not quite well for some time later.

Such cases as these, which could be corroborated by many others, are not to be pooh-poohed because they do not accord with preconceived ideas. Moreover, it appears that Dr. O'Leary of St. Vincent's Hospital and Dr. Brooke of Manchester have independently used similar treatment with success, but it is not pretended for a moment that every case of eczema will be suitable for this method.

I am, Sirs, yours obediently,

December, 1887. H. RADCLIFFE CROCKER.

THE TREATMENT OF INTESTINAL OBSTRUCTION DUE TO IMPACTED GALL-STONE.

To the Editors of THE LANCET.

SIRS,—I congratulate my friend Mr. Thomas Smith on the success of his case; but I wish to make public an easier way of dealing with such a case than that of opening the intestine. I have used it in one case successfully. It consists in passing a fine needle through the wall of the intestine from below (that is, from the empty part of the intestine) into the gall-stone. The stone is thus easily and immediately split up into fragments and passes readily along the intestine, and the grave complication of opening the intestine is rendered unnecessary. The operation is, in fact, little more than an exploratory incision.

I am, Sirs, yours truly,

The Crescent, Birmingham, Dec. 2nd, 1887. LAWSON TAIT.

LIVERPOOL.

(From our own Correspondent.)

POPULAR LECTURES BY PROFESSORS AND LECTURERS OF UNIVERSITY COLLEGE, LIVERPOOL.

DURING the last three months a course of eight lectures on the Structure and Functions of the Human Body in Health and Disease has been given by some of the professors of the Liverpool University College. It was commenced by Professor Herdman, whose subject was the "General Structure of the Animal Body." Professor Banks followed with the "Nutritive System and Digestion"; and Professor Caton with the "Circulation and Purification of the Blood." Mr. Harvey Gibson discoursed upon the "Nature and Uses of Food," Mr. Paul on "Work and Recreation," Dr. Barron on the "Seeds of Disease," Professor Shaw on the "Structures we Inhabit," Dr Hope on "Common Sanitary Defects and the Diseases associated with them." An attentive audience, varying from 900 to 1000, were present at each lecture.

DEATH FROM HYDROPHOBIA.

Another death has occurred from hydrophobia, the victim being a cabdriver, aged forty-two years, who lived in a

Digitized by Google

street in the centre of the city. Three months ago he was followed home by a white fox-terrier; he put it in the cellar for the night, and next morning was feeding it, when it snapped at his right hand and slightly scratched the forefinger. He sucked the scratch, and after putting some wax upon it, took no further notice, following his usual occupation up till the 28th ult., when he complained of being unwell, and stayed at home the two following days. He was removed to the Royal Infirmary, where he died the same day with all the usual symptoms of hydrophobia. A post-mortem examination was made by Dr. Barron, pathologist to the infirmary, who found congestion of the base of the left lung. He removed the spinal cord for microscopical examination.

CITY MEAT SUPPLY, AND THE METHOD OF SUPERVISION THEREOF.

Dr. Hope, the assistant medical officer of health, read a paper at the last meeting of the Medical Institution on a very important subject: "Our Meat Supply, and the means adopted to ensure its wholesome quantity." Some idea of the vast quantity of the work done may be gathered from the following figures, which were circulated among the members. The total quantity of live cattle, sheep, and pigs imported into Liverpool from Canada, United States, Spain and Portugal, and Ireland during the year 1886 was:—

—	From Canada.	United States.	Spain and Portugal.	Ireland.	Total.
Cattle	21,837	47,754	642	268,284	338,517
Calves	7	1	—	4,634	4,642
Sheep and lambs	43,641	2,891	—	410,342	456,874
Swine	70	—	—	128,525	128,595

The following are the quantities (cwt.) of dead meat—viz., mutton and beef—imported into Liverpool from the Argentine Republic, United States, and Canada, during the year 1886:—

—	Argentine Republic.	United States.	Canada.	Total.
Beef (fresh)	1,044	615,088	10,014	626,146
Mutton ,, ...	45,036	5,375	52	50,463

(Excluding bacon, hams, tinned meat, &c.)

The number of animals slaughtered within the city during 1886 at the Abbatoir Company's premises, at the fourteen private slaughter-houses in new parts, and at the seventeen private slaughter-houses in old parts of the city, were:—

—	Cattle.	Sheep.	Lambs.	Calves.	Pigs.
Abattoir	34,586	207,163*	—	16,098	16,320
Slaughter-houses in new parts	4,165	14,685	4,446	365	11,735
Slaughter-houses in old parts	6,353	18,122	5,078	12,080	34,305

* Including lambs.

THE LATE EDWARD PARKER, F.R.C.S. EDIN.

The somewhat sudden death of this gentleman after a short illness was received with much regret by a large circle of professional and other friends. The deceased, who was in his sixty-ninth year, received his medical education in Edinburgh nearly fifty years ago, and, coming to Liverpool, was one of the first surgeons of the then newly established Northern Hospital. He commenced practice later on in Kirkdale, which was then a pleasant suburb northwards of Liverpool, but for many years past built upon and absorbed into the city. In 1845 he obtained the appointment of surgeon to the industrial schools of the parish of Liverpool, situated at Kirkdale, which appointment he held up to the time of his death. He was also for twenty-four years surgeon to the Northern Division of the Liverpool Police, and from 1869 till recently he was surgeon to the borough gaol at Walton-on-the-Hill. He had also at one time a considerable private practice, and, being punctual, exact, and very painstaking, he was enabled to perform all the various duties involved in these public and private engagements with credit to himself and satisfaction to his patients. Some weeks ago he took a chill, which was followed by a severe attack of pneumonia, which, acting upon a somewhat weak heart, compelled him to take to his bed. He was attended by Dr. William Carter, and a few days before his death was able to sit up, and appeared to be approaching convalescence. On the morning of the 1st inst. he was seized with severe abdominal pain, and expressed an opinion to his son that he was dying from perforation of the bowel. This subsequently proved to be correct, an opening being found in the duodenum just beyond the pyloric end of the stomach. His funeral, which at his expressed wish was of the very simplest character, was numerously attended by medical friends and representatives from the Industrial Schools and Liverpool police. Mr. Parker was twice married; he leaves a widow, five sons, and a daughter. Two of the sons are surgeons, one being Mr. Rushton Parker, the well-known Professor of Surgery in Liverpool University College; the other, Mr. Wm. R. Parker, is in practice at Kendal.

WORKMEN'S GRATITUDE TO THE EYE AND EAR HOSPITALS.

The local branch of the Boiler-makers and Iron Shipbuilders' Society have set an example well worthy of imitation elsewhere. They have celebrated the Queen's Jubilee in a manner which, to use the words of a local daily paper, does credit to their thoughtfulness and sense of gratitude. The scheme took the form of a Jubilee voluntary gift from the members of the Society to the Birkenhead Eye and Ear Hospital and the Liverpool Eye and Ear Infirmary. These men are, as is well known, more peculiarly liable to accidents, especially to their eyes and ears. A sum of £21 was subscribed, of which £15 15s. were given to the Liverpool institution and £5 5s. to that of Birkenhead. In addition to this, the former institution was presented with a splendid electric battery, supplied by an eminent London firm at a cost of £10 10s. Such an illustration of the gratitude of working men is most refreshing.

FLOGGING GAROTTERS.

Mr. Justice Day, who presided at the recent assizes as well as the two preceding, is a firm believer in the deterrent power of the "cat," and is averse to long terms of imprisonment, especially for the younger prisoners. Following this view, which so far as this locality is concerned would appear to be well founded, a number of prisoners who had been sentenced to corporal punishment, in addition to short terms of imprisonment, were recently flogged in H.M. prison, Walton-on-the-Hill. The skin is rarely broken, but there is always some cutaneous hæmorrhage where the strokes fall. In a series of eighty cases no ill effects have followed.

Liverpool, Dec. 6th.

NORTHERN COUNTIES NOTES.

(From our own Correspondent.)

FEVER IN NEWCASTLE.

THE febrile epidemic in Newcastle still continues, some practitioners having as many as ten or fifteen cases on their lists. Although the weather has been fine for the season, it has been changeable, high winds alternating with hoar frosts and frequently a damp atmosphere. The death-rate has been high the last few weeks, but I do not think it is so much owing to fever as to a high mortality in the aged and weak. There has been a rather serious outbreak of scarlet fever in the children's wards of the Newcastle Workhouse. Last week as many as 178 had been attacked. Fortunately the type is mild, and I have not heard of any deaths to-day. I hear that the epidemic is subsiding. The disease was, as usual, imported by an outside waif.

GATESHEAD CHILDREN'S HOSPITAL.

The foundation and Jubilee memorial stones of the Gateshead Children's Hospital were laid on Friday last in presence

Digitized by Google

of a large and influential assembly. The weather was fine, but a strong piercing wind blew over the site, and made matters were anything but pleasant for visitors to the ceremony. Up to the present sufficient has been received to make building provision for twelve beds and to leave a sum towards the endowment fund, which, it is to be hoped, will soon be augmented.

SPREAD OF SMALL-POX IN YORKSHIRE COLLIERIES.

Considerable alarm is being occasioned by the spread of small-pox in some of the Yorkshire colliery districts, where the small cottages are crowded with lodgers. On Saturday last fresh outbreaks were reported at Birdwell and Broomhill, near Wombell, where on Friday the authorities were compelled to board a cottage round to isolate it. At several large collieries workmen from infected families have been stopped. Serious interference with trade is anticipated.

Newcastle-on-Tyne, Dec. 6th.

EDINBURGH.

(From our own Correspondent.)

ROYAL COLLEGE OF PHYSICIANS.

AT the annual general meeting of the Fellows which took place last week, the election of office-bearers in the College was the chief business of importance. Sir Douglas Maclagan, who has for two years occupied the presidential chair, retires at this time on the completion of his term of office, but retains a deliberative voice in the affairs of the College by his appointment as Vice-President. His place as President has been taken by Dr. R. Peel Ritchie, one of the senior Fellows, whose long experience in the Council and as treasurer to the College has given him an intimate knowledge of its affairs, and whose careful cultivation of its best interests in the past, renders him peculiarly well fitted to act yet more directly as their guardian and conservator during his two years' term of office as President. The other officers of the College are as follows:—Treasurer: Dr. P. A. Young. Secretary: Dr. G. A. Gibson. Librarian: Dr. G. W. Balfour. Curator of Museum: Dr. T. A. G. Balfour. Curator of Laboratory: Dr. J. Batty Tuke.

THE VACANT ASSESSORSHIP AT ST. ANDREWS.

Considerable interest is felt in Edinburgh in regard to the election, now pending, of an assessor of the General Council of the University of St. Andrews, who will represent that body in the deliberations of the University Court. Dr. John Duncan, M.A., LL.D., is one of the candidates for the vacant office, whose high position in the profession in Scotland, no less than the great services he has rendered in favouring the progress and developing the stability of the Edinburgh School, specially point him out as well fitted to hold an important post, in which his intimate knowledge of the Scottish University system and its requirements will make his services invaluable. His opponent, Viscount Cross, has already held office as assessor; and it is felt keenly by medical graduates of St. Andrews that the interests of medicine in that University require a more thorough representation than they could obtain during a layman's tenure of office.

THE VICTORIA DISPENSARY.

Under the above name a new charitable institution has been established in Edinburgh, which bids fair to take a useful place among the medical charities of the city. It is specially devoted to the treatment of consumption and diseases of the chest, for which cases solely it is intended. It will, therefore, in no way trench on the useful work already done among our poorer classes by the many sister institutions now flourishing around it, but rather relieve them from th econgestion of chest cases that tend to bulk too large in proportion to other branches of their remedial work. The want of such an institution has long been felt in the city on account of the great ravages committed by phthisis, particularly in that class of people who, coming from healthy country districts, fall only too easy and too early a prey to the evil influences of the narrowed physical surroundings of their city life. The new dispensary is situated in Bank-street, in the central district of the city, and is fortunate in possessing light and airy waiting and consulting rooms, which have been brightly and tastefully decorated for the reception of patients. The institution has been placed under the charge of Dr. R. W. Philip, whose recent researches on the Etiology of Phthisis, submitted in the form of a thesis for the Doctorate in Medicine to the University, received the University Gold Medal, the highest honour attainable by its graduates. Dr. Philip also received in recognition of his work the Triennial Gunning Prize in Medicine, a bursary recently founded for the encouragement of original research in connexion with the practice of medicine, and awarded to the most eligible competitive thesis presented within the specified period.

Edinburgh, Dec. 6th.

DUBLIN.

(From our own Correspondent.)

ILLNESS OF SIR CHARLES CAMERON.

THIS gentleman was taken seriously ill last week, and for some time his life was in imminent danger. It is gratifying, however, to be able to state that his condition has considerably improved, and it is confidently expected that in a short time he will be able to resume his ordinary duties. I may add that there is no member of the profession in Dublin better liked both by his brethren and the community at large than Sir Charles Cameron, and a termination to his career of usefulness would be regarded as a national calamity.

DEATHS OF BRIGADE-SURGEON GRAY, SURGEON-MAJOR PUREFOY, AND DR. WHISTLER.

During the past week three Fellows of the Royal College of Surgeons in Ireland have died—viz., Brigade-Surgeon Joseph Gray (retired), Surgeon-Major J. W. Purefoy, and Dr. Whistler of Bray. The last-named gentleman met with his death under distressing circumstances, being killed by an accident in the hunting field last Saturday. Surgeon-Major Purefoy had only three weeks since returned from Trinidad, and died after a short iliness. He was buried at Lucan, where his father, the late Dr. T. Purefoy, practised for many years. The funeral *cortège* was preceded by a corps of the Liverpool Regiment, the band playing Chopin's Funeral March and the Dead March in Saul, and was followed by a detachment of the Army Medical Corps, headed by Surgeon-General Hassard, principal medical officer in Ireland, and officers of the Medical Staff serving in Dublin. On the same day the funeral of Dr. Whistler of Bray, who died at an advanced age, took place. The deceased was a graduate in Arts and Medicine of the University of Dublin, and obtained the Fellowship of the College of Surgeons forty-two years ago. He was a well-known figure at the annual meetings of the Fellows of the College of Surgeons, and took an active part in its proceedings.

SCIENCE AND ART MUSEUM, DUBLIN.

Dr. R. Scharff, an assistant to the Museum for some time past, has been appointed to the vacant curatorship. Dr. Scharff studied at Edinburgh, where he obtained the degree of Bachelor of Science, also in London under Professor Ray Lankester, and worked in the British Museum under Professor Flower, F.R.S. He has written many papers on zoological subjects, and for some time acted as vice-president of the Conchological Society of Great Britain and Ireland.

NATIONAL CHILDREN'S HOSPITAL, DUBLIN.

A bazaar and fancy fair in aid of the funds of this hospital will be held next week. There is a debt still due on the institution amounting to £1500, and it is confidently expected that a considerable amount will be obtained for a very deserving charity.

SMALL-POX IN DUBLIN.

Three cases of this disease were admitted to hospital during the week ending the 26th ult., being one over the admissions for the preceding week. There are seven cases at present under treatment in hospital, but so far only one death has occurred.

EPIDEMIC OF MEASLES IN BALTIMORE, NEAR SKIBBEREEN.

An epidemic of measles of a very dangerous type has broken out in this place, and numerous deaths have resulted. A peculiarity of the affection is that it attacks adults as well

Digitized by Google

as children; in the latter it is complicated with congestion of the lungs. Dr. Jennings, medical officer of the district, is using every exertion to prevent intercourse with the infected families, as, should the disease spread to the adjacent town of Skibbereen, the results would be very serious indeed.

The total amount collected for the Jubilee Fund in connexion with the Royal Medical Benevolent Fund Society of Ireland has been £129 8s., which, after payment of the necessary expenses, will be distributed before Christmas.

The opening meeting of the Scientific Association in connexion with the Royal College of Surgeons' Medical School will be held to-morrow (Wednesday) evening in the Albert Hall of the College.

Dr. Ball has resigned the post of medical officer to the South City Dispensary District, Dublin Union. An election for his successor will take place on the 20th inst.

Dr. B. Kennedy has been elected resident medical officer and apothecary, North Dublin Union, at a salary of £200 a year, with furnished residence, &c.

Dublin, Dec. 6th.

(From our Paris Correspondent.)

DIPHTHERIA.

ACCORDING to the researches lately communicated to the Academy of Sciences by Dr. Teissier of Lyons, the author believes that diphtheria is, above all, an infectious malady, the germ of which, being transmitted through the medium of atmospheric dust, is absorbed through the respiratory organs. The dust emanating from manure heaps, collections of rags or of straw, are particularly favourable for such transmission, as they constitute excellent media for the culture of the pathogenic germ. The pigeon and the common fowl seem to be the most active agents for the dissemination of the germs from these different infectious foci. Among the other cases which contribute to favour the receptivity of the germ, cold occupies the first place (79 out of 132), Dr. Teissier, however, remarks that the humidity of the air constitutes, without any doubt, a condition extremely propitious for the multiplication and dissemination of the germs of diphtheria.

CONFINED AIR AND THE DEVELOPMENT OF PHTHISIS.

At the meeting of the Academy of Sciences of last week, Professor Brown-Séquard spoke upon a subject that he had commenced in 1869 to demonstrate—namely, the influence of confined air on the development of pulmonary phthisis. The learned Professor had performed experiments on a number of guinea-pigs, which he divided into two series. In the one series, after having inoculated the animals with tuberculous matter, they were placed in the most favourable conditions as to bedding, alimentation, and aeration. They lived at liberty under a shed opening into a garden, and where the bedding was frequently renewed. Not one of them (numbering more than a hundred) was affected by the inoculation. They manifested no sign of phthisis, and remained perfectly healthy. The second series, however, which were inoculated in the same manner, but which were condemned to live in closed laboratories, where the air was confined; nearly all died from phthisis. After having shown the advantages which would accrue to phthisical patients were they to live as much as possible in the open air, Dr. Brown-Séquard presented an ingenious apparatus which he invented in conjunction with M. d'Arsonval, the object of which is to remove from a room the expired air of phthisical patients. This apparatus is composed of several parts, the essential one of which is bell-shaped. It is placed at the head of the patient's bed and put into communication by the aid of a tube with a chimney, heated by gas, or a candle, or a lamp, so as to cause a draught. The chimney, which communicates equally by a tube with the external air, draws all the air proceeding from the lungs of the patient and expels it to the exterior in such a manner that it does not mix with the atmosphere of the room.

THE CLEANSING OF CARPETS.

One of the most prolific sources of the propagation of infectious or contagious diseases is, as you have more than once pointed out, the house carpet, which can retain the germs of these diseases. But as the carpets must be cleaned, and as the practice of beating them in the open air is considered a public nuisance, M. Bunel, the principal architect of the Prefecture of Police, was charged to devise some means by which this nuisance might be reduced to a minimum, or, if possible, entirely prevented. M. Bunel submitted an apparatus in the form of a cylinder to the Council of Public Hygiene, in which the carpets are placed, and by a rotatory motion the dust is dislodged. The advantages of this invention over the ordinary method had been approved of; but M. Bunel soon discovered that the dust and other particles escaping from the carpets, instead of being burned as he thought they would be, were utilised in industry for filling cushions, and the finer particles were employed for coating paper hangings, which give them their velvety appearance. This highly objectionable practice was soon brought to the notice of the police authorities, and on the advice of the Council of Hygiene it is ordained that the dust and particles beaten out from carpets should be collected in closed apparatus and burned; but those who may wish to utilise them should have them previously disinfected and then submitted to a current of steam under pressure at a temperature above 100° C., or of sulphurous acid.

Paris, Dec. 6th.

THE SANITARY CONDITION OF VENICE.

(From our Special Correspondent.)

THE question whether Venice may fairly be described as a healthy town is an open one. The admiration, that at times degenerates into fanaticism, with which everyone possessing any artistic perception must view such a town as Venice is apt to obliterate the consideration of those sanitary matters on which our existence depends. Then comes an epidemic of cholera coupled with exaggerated apprehension. No place, perhaps, has been so often described as Venice, and yet little or nothing is known concerning its sanitary condition. The studies on this town, whether with pen or pencil, are generally art studies. A dissertation on the soil-pipes, drains, and cesspits of Venice seems almost a sacrilege. It is, however, none the less necessary, particularly when we consider that the average death-rate for the twenty years from 1861 to 1880 amounted to 30·3 per 1000 of the population. This period comprises several years of foreign domination, of political struggles and revolutions, when, of course, sanitary matters were greatly neglected. Now that independence and peace have been enjoyed for some years a marked improvement has taken place. According to a pamphlet now in course of preparation at the Demographical Department of the Venice Municipality, the mean mortality for the years 1883 to 1886 was only 25·8 per 1000. Yet the mortality for 1886, which included 640 deaths from cholera, amounted to 28·2. Again, according to local statistics, the death-rate for 1884 amounted to 24·6 per 1000; whereas, in the official Government report published at Rome, the death-rate for this year is estimated at 28·90, 28·49, or 26·98 per 1000, according to allowances made for floating population. Taking the present year, I find, during the first quarter, that 29·2 deaths per 1000 per annum were recorded, and the proportion during the second quarter of 1887 fell to 21·8 per 1000. Probably the average death-rate at Venice is now 26 or 27 per 1000. Comparing Venice with the nineteen principal towns of Italy, with populations varying from half a million to 58,000 persons, Venice stands in a position about half-way between the worst and the best, though there are but seven towns that have a larger population in the kingdom.

On discussing the question of the death-rate with Dr. Alex. Menzies, an English resident physician at Venice, the fairness of comparing English and Italian death-rates was raised. Basing his observations on many years' experience of Italian practice, Dr. Menzies insisted very forcibly on the insufficient nutriment of the native diet. Even the better class lived in a wretched manner. They were vegetarians, and bad vegetarians, for they did not eat enough of those vegetables that are the best substitute for meat. Polenta of inferior quality, as is so often the case, is not equal to Scotch oatmeal. Consequently they were the ready victims of any outbreak of illness. Nor do the people possess sufficient stamina to resist illness. Quick to take alarm, with loss of courage and insufficient nutriment, the system was not able

Digitized by Google

to shake off an indisposition which a well-fed Englishman would scarcely feel. Though there is a regular municipal service to inspect all food brought into the town, it is feared, nevertheless, that this is not as fresh as it should be. When the cholera epidemic broke out, some twenty tons of bad food, I was told, had been seized in a day. With similar lack of faith, many persons deny the prevalence of cholera to the extent described. There are a certain number of doctors who are appointed by the municipality to attend on the poor, and their fees amount to about 4s. for each case. When, however, cholera prevails, these doctors receive a fee of £1 for each case,—not for each visit, but for each case. The difference between five francs and twenty-five francs is so great, and the doctors at best are so grievously underpaid, that it is not surprising if, in a country where corruption is not an unknown evil, the public should have suspected that cases were recorded as cholera when the disease was only due to some digestive disturbance, caused probably by bad food. On the other hand, and as opposed to these arguments, it must be borne in mind that the inhabitants of Venice are equally interested, on their side, in making out as good a case as possible for the town, so as not to alarm the foreign visitor, on whose presence and custom they in a great measure depend. It is, therefore, natural that all manner of arguments should be brought forward to lessen the importance of the cholera epidemic. Certainly foreign visitors would not have encountered so grave a risk as many were led to imagine had they gone to Venice when the cholera prevailed. Here, as elsewhere, most of the victims were among the poorer classes—the worst fed and the worst lodged sections of the population. Concerning the food, which is stated to be responsible for many cases of illness erroneously described as cholera, what I saw—not a large quantity—did not seem unfit for consumption. The fried fish shops in the poorer quarters compared very favourably with similar institutions in London. The grease appeared to be of a much better quality than that used in London, and there was a greater variety of fish. In the butchers' shops every piece of meat bore the stamp of the public slaughter-house where it had been inspected; and this is a better system of control than that enforced in England. Visitors may attribute to bad food attacks of intestinal catarrh, which are really due to standing on cold marble floors and to chills caught by going from the heat of the sun into the cool of churches, palaces, or museums.

At Venice, as elsewhere, the high death-rate was attributed to the number of public hospitals and similar institutions, which attract patients from the surrounding provinces. Of course this argument applies also to London, Paris, and other great towns. Nevertheless, it has some weight with respect to Venice; for the proportion of deaths in public institutions for the years 1881-82 amounted to 351 out of 1000 deaths in the town. In 1883 the proportion was 365, and 349 in 1884. On the other hand, in London, during, for instance, the year 1883, the deaths in public institutions amounted to only 205·0 per 1000. This difference, however, may be due not so much to a large influx of patients from the outlying rural districts, as to greater poverty among the mass of the population of Venice itself.

More serious than these questions is the vexed problem of the Venice water supply. In this matter the position of the town is altogether peculiar and exceptional. Wells in Venice are not built so as to collect water from the surrounding soil, but, on the contrary, so as to exclude all such water. Apart from the question of possible contamination, as Venice is built on 114 small islands, divided from one another by 150 canals, all full of salt water, any water derived from the soil would be brackish and undrinkable. A well in Venice consists of an outer well carefully cemented so as to exclude all infiltration. In the centre another smaller well is built. Between the two fine clean sand is introduced. The rain-water collected from the roofs is conducted by pipes to the surface of the sand, and has to filter through till it reaches the bottom of the outer well, and here little holes enable the water to pass into the inner well or channel. In a word, the water supply of Venice consisted of rain water filtered and carefully stored; but in dry seasons this supply would fall short. Then barges were employed to bring water from the river Brenta on the mainland, and the wells thus replenished; now, however, a company has obtained a concession for the water supply of Venice. Iron pipes are placed at the bottom of the lagoon, and the water of the Seriola canal, which is a derivation of the Brenta, brought to Venice, and thus a constant supply is provided to all subscribers. There are reservoirs containing in all 10,000 cubic metres, and the water, under a pressure of three atmospheres, can be delivered to a height of 20 metres. The charge is 60 centimes per cubic metre; but on a very large quantity a reduction is made. There are also 115 public wells where this water is supplied gratuitously. Thus there is no need to fear that the water supply will run short, and in that sense an improvement has been accomplished. Nevertheless, it would have been much safer to have continued to rely on the old system. It suffices to say, not to mention other sources of contamination, that the new water supply receives all the dejections of the town of Padua, with its 47,000 inhabitants. Loud and angry protests have been made against the introduction of water from such a source. Several practitioners have assured me that typhoid fever has notably increased since the new water supply, though I was unable to obtain any statistics either to confirm or to disprove this assertion. The authorities, on their side, assure me that the canal was watched by troops during the cholera epidemic; this precaution, however, would not prevent the town of Padua draining into the Brenta. The best thing that can be said is that it is proposed to alter the source of the water supply, and the municipal authorities believe this indispensable reform will soon be accomplished. There is, however, a tendency to procrastination, and strong public pressure must be brought to bear on this all-important point.

To account for the presence of typhoid fever, however, one is not limited to the water supply. The domestic arrangements are ingeniously contrived to produce the utmost possible mischief. An opportunity was procured me of visiting several houses where cases of typhoid fever had occurred. In one instance, the father, mother, grandmother, and two children lived in one ground-floor room. The flooring had sunk a little below the level of the street, and there were traces of dampness. In the furthest corner of the room there was a sink and a small marble seat. On lifting up the lid of this seat there was seen below it a square masonry shaft. The rough broken pieces of stone or brick were covered with fæcal matter. There was no closet pan, no pipe, only a plain square masonry shaft, and this in a bedroom and living room occupied by five persons! From the sink a pipe went in to this drain and brought back its foul odours. Down this hole the dejections of the typhoid patient were thrown, without any precautions whatever being taken, and without any attempt being made to disinfect them. Over this open drain hung buckets containing water, and round about was the food of the family. When the buckets are empty, they are taken from within a foot or two of a drain soiled with the dejections of a typhoid patient, and thrown down into the public wells and refilled. During the cholera epidemic, the municipality provided buckets and ropes to the public wells, and appointed guardians to watch and prevent persons contaminating the water by casting down their own buckets and ropes. This excellent precaution is now neglected; in fact, I have not seen it applied at any one well, though, of course, I did not visit all the 115 public wells and fountains of Venice.

In another house, where a better class of working men lived, sharing several rooms, and in nowise suffering from overcrowding, I found exactly the same utter want of proper sanitary accommodation. In the kitchen, by the fire, side by side, stood the sink for washing dirty dishes &c., and a marble seat with a circular hole opening into a brick or stone shaft. No pan, no valve, no pipe; as for traps or syphons, of course they were totally out of the question. The closet seat, if such it may be called, was not even walled off from the rest of the kitchen, and, together with the sink-pipe, poisoned the atmosphere of the room. Here also the water buckets stood or were suspended within a few inches of this fever-breeding drain. On inquiry I was informed this was no exceptional case, and that the arrangements of the other houses were the same. The inhabitants were utterly astounded by my questions and investigations. The idea that such things could in any way affect their health had never dawned upon them. This foulness and neglect on the part of the authorities was all the more lamentable as in other respects the homes of the poor are very superior to the habitations of similar classes in the large towns of England. It was impossible not to admire the cleanliness of the bedding, the order of the rooms, the simple neatness of the furniture, the sobriety of the inhabitants, and the care they took of their home. In

Digitized by Google

English workman with twice the income could not make half so good a show. That so worthy a population should be allowed to fall victims to a great number of diseases for want of properly constructed waterclosets and waste water pipes is absolutely inexcusable. This is a criticism, however, that does not apply specially to Venice, but also to a number of other Italian towns, and it will be necessary to revert again to the question of domestic drainage in Italy.

In the meanwhile, and so far as the public sewers or drains of Venice are concerned, these afford special advantages. They are very short, and do not communicate one with the other. Houses possessing wells adjoining a canal drain directly into the water. Those situated in the small bye streets drain into a small sewer built under the street. These sewers are constructed below the water level, and are therefore always quite full of canal water. They constitute, in fact, huge syphons. A few houses have cesspools, but this is exceptional. It will be seen, therefore, that the interiors of the houses are not exposed to the ingress of sewer air generated throughout the town. The nuisance is always a local one, and does not come from any distance. The main difficulty arises from the fact that some of the canals are not affected by the tide. The water therefore becomes very foul, and this is still worse with respect to the small water-logged sewers in the bye streets. Some method of flushing these must be contrived; and with a little engineering skill, and the assistance of the flow of the tide in the neighbouring canals, this should not be impossible. The fact also that the water is salt is, of course, a great protection; but even salt water, in time, becomes foul, and measures for its renewal must be taken. If this were done, and a house-to-house visitation instituted for the purpose of destroying all the drain shafts—I cannot call them pipes—such as I have described, Venice would be one of the most favoured towns in Europe. There is no necessity for cesspools or sewers, therefore no need to endure all the dangers of sewer air; but proper closets must be provided for the houses, and in the meanwhile all foul drains should be destroyed. In some houses there are no drains whatsoever—deep vases are employed and emptied straight into the canal. This is infinitely better than a masonry shaft, which retains on its rough sides the greater part of the soil, and thus permanently infects the surrounding atmosphere.

Of course in some of the better houses English water-closets have been introduced; but I very much question the soundness of the pipes into which they drain, and in any case this only affects a very small part of the population of Venice, though it comprises a large proportion of English visitors. Domestic drainage and the water supply are the two greatest stumbling-blocks to the prosperity of Venice. If the town could be improved in this respect, the number of visitors would be greatly increased and the fears of epidemics disappear. For three years Venice has suffered severely from the absence of its usual visitors, who felt that the town was not safe when cholera was at hand. Indeed, the list of epidemics shows that in 1835 there were 661 cases of cholera and 359 deaths; 3519 cases and 1453 deaths in 1836. In 1837 there were again 344 deaths. Twelve years later, in 1849, the cholera returned to Venice, and there were 6642 cases and 3839 deaths. In 1854 an epidemic commenced, and 86 cases are noted, with 59 deaths, which augmented the following year to 1208 cases and 708 deaths. In 1866 there were 202 cases and 125 deaths, and in 1867 508 cases and 333 deaths. In 1873 some 800 cases and 459 deaths were recorded, and finally we have last year's epidemic. There were also small-pox epidemics in 1870-71, in 1880-81, and in 1884-85. It will be seen, therefore, that measures for the prevention of zymotic diseases are urgently required, and that, in defence of public health and public interests, it is necessary to call attention to these questions.

Venice, Nov., 1887.

EGYPT.

(From our own Correspondent.)

THE SCHOOL OF MEDICINE.

THE Ministry of Public Instruction has recently made some important changes in the management of this school. Instead of nearly all students receiving their medical education gratuitously and living in the school at Government expense, the present scheme provides for 100 paying and 100 non-paying students, and forty holders of annual scholarships. After the present generation of students none will be admitted gratis. The scholarships are given after competitive examination to poor youths, and consist of £25 a year, besides immunity from school fees. This is already a great advance upon the time when, forty years ago, Mahomet Ali Pacha had to fill his schools by bringing in children by force and locking them up as prisoners. Much greater care is being taken in the preliminary education of boys for the eight years before they commence the study of medicine, and it is reasonably hoped that in a few years we shall have a much better educated class of young doctors. These reforms are chiefly due to the activity and intelligence of Yacoub Pacha Artin, the Armenian Under Secretary of State for Education. At the Medical School there are now thirteen native professors, two assistant professors, one Syrian to teach English, a Levantine curator of the museums, and several natives for purposes of minor teaching. Several new laboratories have been constructed, but unfortunately the old dissecting-room has been demolished before the new one has been begun, so that there will be no practical anatomy for this winter. Clinical work in the wards is beginning to be carried out, but it is at present chiefly in the form of bedside lectures. During the last five years ten books have been written in Arabic by the professors, the matter being mostly culled from some well-known French author. The books include Zoology, Inorganic Chemistry, Mineral Chemistry, Medicine, Auscultation and Percussion, Diseases of Children, Materia Medica, Midwifery, Diseases of Pregnant Women and Children, and Legal Medicine. No less than six of these ten volumes bear the name of the director of the School, Issa Pacha Hamdy. A work on Anatomy is now in the press, and contains some very good plates. It is greatly to be regretted that insuperable jealousy prevents the use of Gray's Anatomy, which was translated into Syrian Arabic by the American Mission at Beyrout. Three young Egyptians have lately returned here with the M.D. degree of Paris, and have been given appointments in the Sanitary Department. There are now three medical students at Montpellier and one in Paris, who, like those just mentioned, are being educated at the expense of the Egyptian Government. Students are never sent to London on account of the expense, and it is several years since any were sent to Edinburgh from here.

GOVERNMENT SCHOOLS IN GENERAL.

Twelve schools are now placed formally under medical charge of a native oculist and other medical men. In consequence of their reports it has been determined to close all schools during August and September, it being found that the children suffered most during those months from diarrhœa and the heat of the weather. Gymnasiums and military instructors have also been provided in order to improve both *physique* and *morale* of the children. Until quite lately evening studies were carried on with only one candle for six boys, but lamps have now been provided which give a light equal to twenty candles to every six boys. It is hoped that this, together with other sanitary improvements, may help to diminish the eye disease which is still very rife among the scholars. Among minor details, wooden plank beds with wool mattresses have given way to iron beds and spring mattresses. A more important question is the due filtering of Nile water and attempts to lessen the cases of Bilharzia hæmatobia. Little can be done until the children are taught the elements of hygiene and cease to believe that unfiltered water is more healthy than after it is rendered colourless. The following numbers show a decided improvement in the ophthalmia of the various schools:—

Percentage of diseases.	Digestive canal.	Eye.	Respiratory.	Urinary.	Skin.	Various.
1884	29	58·0	12·0	2·0	2·4	8
1885	25	29·0	8·0	1·8	1·0	9
1886	46	23·7	5·9	3·9	3·0	22

THE LATE VALENTINE BAKER PACHA.

The Egyptian police, and a very large circle of admiring friends here and elsewhere, are now mourning the sudden death of General Baker. As some inaccurate accounts

Digitized by Google

of his decease have been telegraphed it may be well here to give the correct version. Upon Nov. 5th the General left Cairo for Port Said to meet his daughter, who was arriving from England. For the next four days he suffered from very slight fever, possibly of malarial origin. He had no fever after Nov. 9th, and then spent six days at Suez convalescent. The fever is only mentioned here to show that it had nothing to do with his death. Upon the 16th inst. he steamed up the Canal in a police launch from Suez towards Tel-el-Kebir, and after a quiet day and a light dinner he went to his cabin apparently quite well at 10.30 P.M. At 2 A.M. he called his daughter, complaining of intense pain in the left chest and back, and stating that he had had no sleep on account of the mosquitoes. The pain was of a very oppressive nature, and increased in severity in spite of fomentations, stimulants, liniments, and a small dose of chlorodyne, administered by the ladies present. Pain was also present in the left shoulder and arm, and it was then remembered that the General had complained of this symptom for two days previously. A great sense of faintness, dyspnœa, lividity of face and hands were also noted, and at 5 A.M. death occurred quite suddenly. His sufferings for three hours were very acute, but were borne with uncomplaining fortitude. His ordinary medical attendant was at once telegraphed for from Cairo, and had no difficulty in certifying angina pectoris as the cause of death. The General had had no previous attack of angina, but it was suspected that he had fatty degeneration of the muscular tissue of the heart. During the past two years he had had some sudden attacks of faintness without apparent cause, inability to take rapid exercise on foot or on horseback, and several minor symptoms, which the patient himself thought to be dyspeptic. No valvular disease had ever been discovered, but he had a weak first sound of the heart. His friends, who, like the writer, had witnessed his untiring activity ten years ago during the Russo-Turkish war, had not failed to notice an ever-increasing physical inertia, though his mind retained to the last an able, statesmanlike grasp of every subject submitted to him. He and his family had suffered much while in Egypt. It will be remembered that in the spring of 1884 he was severely wounded at the battle of El Teb, and upon this occasion he remained six hours in the saddle, with a grape-shot weighing four ounces lodged deeply under his right eye. A year later his wife died at Assouan of a relapse during enteric fever, and his elder daughter also succumbed to severe ulceration of the great intestine during convalescence from enteric fever in Cairo. His only remaining child contracted the disease from the same insanitary house, and recovered after a severe attack.

SIMPLE CONTINUED FEVER.

This fever in Cairo has not yet disappeared, but the cases now occurring are of a much milder type, as if at the end of an epidemic. There are two classes of cases—those apparently due to malaria, and well known as sporadic cases every autumn in Egypt, and others associated with a slight erythema of face, fleeting sore-throat, and desquamation of the hands and face. These eruptive cases are very like scarlatina, and are very probably an extremely mild and innocuous variety of dengue.

Cairo, Nov. 21st.

NEW YORK.

(From our own Correspondent.)

CHOLERA IN NEW YORK HARBOUR.

ON Sept. 23rd the ship *Alesia*, from the Italian ports of Palermo and Naples, arrived in the harbour of New York, after a voyage of twelve days. She had on board 560 passengers, and had lost by cholera on the voyage six other passengers. Of those on board, thirty-five were subsequently affected with cholera at quarantine, of whom nineteen died. On arrival the passengers were landed at Hoffman Island, where they were detained under observation, and the sick were sent to Swinburn Island. It is necessary to state that the New York quarantine establishment consists of: (1) The residence of the Health Officer on Staten Island; (2) Hoffman Island, an artificial island, originally constructed for the storage and disinfection of cargo; (3) Swinburn Island, with its hospitals for the cure of the sick, and until recently (4) a floating hospital for yellow fever. This latter vessel has been removed. The passengers of the *Alesia* were first transferred from the vessel to Hoffman Island, which was in a state of wretched dilapidation. Having been partially fitted with two storehouses for goods, it had not been occupied for many years, and had consequently been allowed to fall into decay. The accommodation for passengers was of a most imperfect kind, and it is not surprising that new cases of cholera continued to occur. There was no proper isolation of the sick from the well, any more than there was on shipboard, and the disease finally died out. The passengers were detained, however, for about two months, though the ship was cleansed and allowed to proceed to her destination. Two weeks after the arrival of the *Alesia*, the *Britannia*, of the same line, arrived, and was detained at quarantine, where cases of cholera developed among her passengers, who are at present under observation. No case of cholera has now occurred for upwards of two weeks, and it seems quite certain that the last germs have been destroyed. The arrival of cholera at our port will prove useful, for it has stimulated proper inquiry as to the condition of our quarantine system and its value. The exposure of this country to direct importation of the infection is very great. There are three lines of steamers between the infected Italian ports and this port, which bring thousands of immigrants, who, in general, represent the lowest class of the populations of those cities. Though our quarantine has undoubtedly prevented the immediate landing of immigrants with their infected clothing, and thus saved the country from the threatened invasion, yet the fact has now been demonstrated that the quarantine of this port is altogether unfit for its purpose. Efforts will be immediately taken to have the entire establishment placed in working condition, so that cargo can be rapidly handled, passengers separated and supervised, and the sick promptly treated. The condition of the New York quarantine naturally interests the Western States quite as much as it does New York, for the great mass of immigrants now arrive with railroad tickets in hand, and hence pass on directly to their destination, which is usually some city of the "Far West." It is in western cities, a thousand miles west of New York, where they first unpack their clothing and household goods packed in their Italian homes. Hence it is that the western States manifest such interest in the quarantine of this port.

AMERICAN PUBLIC HEALTH ASSOCIATION.

This body, now one of the most important national associations, has just completed its fifteenth annual session at Memphis, Tennessee. The session was occupied chiefly with questions relating to practical work of the various health boards of the country. The president, Dr. Sternberg, had just returned from Brazil, where he had been investigating the claims of Freire and Valle to the discovery of the germ of yellow fever. He did not indicate the results of his inquiry.

ROYAL COLLEGE OF SURGEONS.

AT an ordinary meeting of the Council, held on Thursday, the 8th of December, the Minutes of the Council of the 10th of November were read and confirmed.

As recommended by the Museum Committee, the appointment of Pathological Curator was postponed, and the services of Mr. Eve are retained until Midsummer-day next. An additional assistant is to be appointed in the pathological department of the museum to assist in procuring, examining, and preparing pathological specimens, at a salary at the rate of £150 a year; and he will be required to devote to the duties of the office from five to six hours per diem. The three new work-rooms on the fourth floor are to be devoted to pathological investigation by Fellows and Members of the College under the control of the Museum Committee. (This is not intended to include experiments on animals.)

On the report of the Committee of Management, it was agreed that the University of Otago, Dunedin, New Zealand, be recognised as fulfilling the requirements of the Board in regard to professional study for the diplomas of the two Colleges.

Digitized by Google

The sixth report, dated Nov. 29th, 1887, of the Committee on the Extension of the College premises, was adopted. The committee recommend the Council to authorise an expenditure of £1179 in providing additional accommodation and fittings for the Library.

Mr. Christopher Heath was re-elected a member of the Court of Examiners in Surgery.

The best thanks of the Council were given to Sir James Paget and Sir Joseph Lister for the delivery of the Morton and the Bradshawe Lectures respectively, and they were requested to publish them.

The Secretary reported the receipt from Messrs. Lawrance, Graham, and Long of the portrait by Richmond of the late Mr. Quain, bequeathed by him to the College. The bust of Mr. Quain, by Woolmer, offered by Miss Dickinson, was accepted with thanks by the Council.

A letter of the 23rd ult. from the Lords of the Privy Council, forwarding a copy of the statement relating to the Supplemental Charter prepared by the Association of Fellows, and requesting to be favoured with any remarks thereon which the Council may have to offer was read, and it was referred to the President and Vice-Presidents to report to the Council at an extraordinary meeting of the Council to be held on Thursday, Jan. 5th.

A letter of the 15th ult. from Mr. Wyndham A. Bewes was read, submitting to the Council the draft of a section which it is proposed to introduce into a Bill for the suppression of indecent publications and advertisements, and inquiring whether the same will meet with the support of the Council. The following resolution was passed: "The Council do not feel prepared to express an opinion on the subject of the proposed section."

Letters from a medical officer of the army were read, requesting the support of the Council on behalf of the officers of the Army Medical Department in their endeavour to obtain military rank and status. The following resolution was passed thereon: "That the Council, whilst feeling an interest in the officers of the Army Medical Department, are not prepared to express an opinion on the questions submitted to them."

The following motion, brought forward by Mr. Hutchinson, seconded by Mr. Bryant, was carried: "That it be referred to a committee to consider and report to the Council on the desirability of altering the regulation relating to the procedure in the election of members of the Court of Examiners, in order that the same may be modified so as to secure that no one be elected unless he receive the votes of a majority of the members of the Council present at the meeting."

The following resolution was also passed: "That, in the opinion of the Council of the Royal College of Surgeons, it is most objectionable that Fellows and Members of the College should allow their names to be advertised in connexion with medical or surgical subjects in popular journals."

Medical News.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following Members having passed the final examination for the Fellowship on Nov. 24th, 25th, 26th, and 27th, 1887, were at a meeting of the Council, held on Thursday, Dec. 8th, duly admitted Fellows of the College:—

Taylor, H. H., L.R.C.P.Lond., Consumption Hospital, Brompton; date of Membership, July 22nd, 1880.
Waldy, J., L.R.C.P.Lond., Green-pk., Darlington; July 18th, 1882.
Townsend, S. Chapman, Burleigh-st., Strand; Nov. 14th, 1883.
Thomas, D. L.R.C.P.Lond., Cefnbanal, Tregaron, Aberystwith; April 23rd, 1884.
Murray, G. A. Everett, L.R.C.P.Lond., Chelsea-gardens; April 28th, 1884.
Roberts, J. Reid, M.B.Durh., Suez, Egypt; July 28th, 1884.
Cropley, H. L.S.A., The Hospital, Rotherham; Aug. 6th, 1884.
Smith, F. J., M.B.Oxon, West-st., Finsbury-circus; April 28th, 1885.
Shadbolt, Lionel Pierrepont, L.R.C.P.Lond., Beechcroft, Chislehurst; Aug. 5th, 1885.
Hawkins, F. Stanhope, M.B.Oxon, Trinity-sq.; July 26th, 1886.
Middleton, A. Hancock, M.D., Q.U.I., Athgo-park, Shankill, co. Dublin; January 17th, 1887.

Two other candidates passed the examination, but not having attained the legal age (twenty-five) will receive their diplomas at future meetings of the Council. Three were referred for six months and sixteen for one year.

The following gentleman having undergone the necessary examination in Surgery for the diploma, and, having since obtained a medical qualification was at the same meeting admitted a Member of the College:—

Cunningham, J., L.S.A., Rudgrave-place, Egremont, Cheshire.

At a meeting of the Council of the College on Thursday, the 8th inst., the following gentlemen were elected Examiners under the Combined Scheme for the ensuing year:—*First Examination:* Elementary Anatomy—Messrs. Ballance, Bruce Clarke, Arthur Hensman, W. Arbuthnot Lane, and Charles Stonham. Elementary Physiology—Edwin Hurry Fenwick and William Dobinson Halliburton. *Second Examination:* Anatomy—Messrs. W. H. Bennett, Rickman John Godlee, F. Howard Marsh, and Edmund Owen. Physiology—Messrs. Golding-Bird, B. Thompson Lowne, and Jeremiah McCarthy. *Third Examination:* Midwifery—Drs. William Duncan, Walter Spencer Griffith, George Ernest Herman, John Baptiste Potter. *First Fellowship Examination:* Anatomy—Messrs. Wm. Anderson, Davies-Colley, Rickman J. Godlee, Henry Morris, and Edmund Owen. Physiology: Messrs. Golding-Bird, Benjamin Thompson Lowne, Jeremiah McCarthy, and Gerald Francis Yeo.

ROYAL INSTITUTION OF GREAT BRITAIN.—Mr. and Mrs. Victor Horsley, and Mr. George Lindsay Johnson, have been elected Members of the Royal Institution.

THE governors of the Essex and Colchester Hospital have decided to appoint a paid physician to that institution, at a stipend of £200 a year.

MEDICAL MAGISTRATE.—The name of Mr. G. A. Phillips, M.R.C.S., L.S.A., has been placed upon the Commission of the Peace for the borough of Walsall.

THE death is announced of Mr. John Benjamin Dancer, a Manchester optician, who, it is stated, constructed the first thermometer made in England with any pretensions to accuracy.

SCARLATINA is reported to have broken out among the boys of the *Impregnable* training ship to such an extent that orders have been given countermanding the Christmas holidays, and all the boys have been prohibited from leaving the ship.

HOSPITAL SATURDAY.—On Saturday, Dec. 3rd, the annual Hospital Saturday collection was made for the benefit of the Wolverhampton and Staffordshire General Hospital and of the Wolverhampton Eye Infirmary. For the latter the sum of £226 14*s.* 9*d.* was received, and for the former £1526 1*s.* 2*d.*, being an excess of last year's collection of £210.

THE DENTAL HOSPITAL OF LONDON.—The annual dinner of the staff and students of the Dental Hospital and School of Dental Surgery was held on the 3rd inst., Mr. G. Gregson in the chair. Amongst those present were Sir Edwin Saunders, Dr. Julius Pollock, Dr. Pearce Gould, Mr. Morton Smale, Mr. R. Hepburn, Mr. Underwood, and Mr. J. F. Pink (Secretary).

THE SMALL-POX EPIDEMIC AT SHEFFIELD.—During last week forty-two fresh cases of small-pox were removed by the ambulance to the Winter-street Hospital. Thirty-two convalescent patients were also conveyed to Totley. Altogether, during the week, 106 patients, either suffering or convalescent from the disease, were moved to or from the two hospitals in the borough ambulances, under the direction of Dr. Willey.

SANITARY INSPECTORS.—A meeting of the Association of Public Sanitary Inspectors was held on the 3rd inst. in the Westminster Town Hall, under the presidency of Mr. J. H. Alexander, chief sanitary inspector for Shoreditch. It was unanimously resolved to hold the third provincial meeting in Liverpool. Dr. Collingridge, medical officer of health of the Port of London, delivered an address on the Duties of Port Inspectors of Nuisances. A discussion followed.

Digitized by Google

VACCINATION GRANTS.—Mr. H. T. Woodd, Calstock, Cornwall, and Mr. George Fisher, Shere, Surrey, have been awarded the Government grant for efficient vaccination in their respective districts, the latter for the fifth time.

SMALL-POX IN SPAIN.—For some time past an epidemic of small-pox has been spreading in Spain. Vaccination is not compulsory, and large numbers of the poorer classes in the towns and rural districts have never been vaccinated. In the first twenty days of November, according to official statistics, 200 deaths from the disease have taken place in Madrid alone, which has a population of about half a million. The majority of cases are under treatment in the civil hospital, but about forty cases have occurred among the troops.

BEQUESTS.—The late Miss M'Keller has left £2000 each to the following hospitals:—The London Hospital, St. Thomas's Hospital, St. George's Hospital, the Westminster Hospital, Charing-cross Hospital, St. Mary's Hospital, and the National Hospital for the Paralysed and Epileptic. At a quarterly court of the governors of the Brompton Consumption Hospital on the 24th ult. the following legacies were announced:—General Ramsey, £200; Major Hooper, £500; Miss M'Keller, £1000 (reversionary); Mrs. Cook, £1000; Miss Hore, £250; Mrs. Pownall, £200; and Mrs. Levien, £500 (duty free). The late Mr. James Wishart, of Leith, has bequeathed £300 to the Edinburgh Royal Infirmary and £250 to the Leith Hospital.

THE SURGICAL AID SOCIETY.—The annual meeting of this Society was held at the City Terminus Hotel on Wednesday last, the Lord Mayor presiding. His Lordship, in congratulating the supporters of the Society on its prosperous condition after the completion of a quarter of a century, stated that the average number of patients assisted each week was 142, the total for the year being 7394, as against 6412 in the previous year. Last year 10,400 surgical appliances had been given to the poor, and the total number distributed since 1862 was 689,704. The annual report gave a very encouraging account of the work of the Society.

BRITISH MEDICAL BENEVOLENT FUND.—The monthly meeting of this useful charity was held on the 29th ult., when there were twenty-six applicants for grants; and the balance at the disposal of the committee would have been overdrawn but for the opportune donation of £20 by an old and valued subscriber. The sum of £142 was voted away to fourteen applicants, and two cases were postponed for further inquiries. Two cases merit mention. In one, a paralysed medical man had a wife and six children entirely dependent upon him, and the sum of £13 was voted and ordered to be sent in weekly instalments of 10*s.*, with leave to apply again in six months; and in the other, a grant was made to enable a widow to obtain needful change for a son suffering from phthisis.

PRESENTATIONS.—On Friday, Dec. 2nd, Dr. Bell, senior medical officer of the Bradford Eye and Ear Hospital, was presented with a large and admirable portrait of himself, which had been subscribed for by a number of gentlemen. The Mayor of Bradford, who made the presentation, said that he was exceedingly glad to act as the mouthpiece of those who thus desired to show their appreciation of the Doctor's unstinted services to the hospital for over thirty years. Dr. Bell, in returning thanks, referred to the constant growth of the hospital, which he attributed to the earnestness of the committee and of the staff. He hoped the portrait might remain in the hospital, which had been the scene of the best part of his public work. Sir Jacob Behrens said the committee accepted the portrait with the greatest pleasure.—Dr. R. Lawson Roberts was on the 23rd ult. presented with a silver salver by the workmen of the New British Iron Company's Wynnstay Colleries, Acrefair Ironworks, and Plasynwerm Brickworks, as a token of their regard and appreciation of his services as the medical officer of the works.

VACCINATION IN EASTBOURNE.—The Local Government Board recently called upon the guardians of the Eastbourne Union to explain the delay attending certain vaccination prosecutions. The guardians have, in their reply, referred the cause to the opposition to the compulsory clauses of the Act on the part of the working classes, to the spread of anti-vaccination literature in the shape of leaflets, to illness amongst infants, and to the removal of families from one district to another.

Notes, Short Comments, & Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

All communications relating to the editorial business of the journal must be addressed "To the Editors."

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news-paragraphs should be marked and addressed to the Sub-Editor.

Letters relating to the publication, sale, and advertising departments of THE LANCET *to be addressed "to the Publisher."*

We cannot undertake to return MSS. not used.

"INQUEST EXTRAORDINARY."

To the Editors of THE LANCET.

SIRS,—Will you kindly allow me to give a short history of the facts in connexion with the post-mortem on the murdered body of Mr. Gold, in order to correct a slight inaccuracy in Mr. Thomas Bond's letter to you appearing in last week's LANCET, and to show that there is a basis of truth in Mr. Coroner Baxter's statement that "the medical men were unable to discover the aperture of entry of the bullet fired into Mr. Gold's body by the murderer Lefroy."

Mr. Gold's body was found in Balcombe Tunnel, and removed to the coach-house at the inn adjoining Balcombe station. Dr. Thomas Byass of Cuckfield saw the body, and was ordered to make the post-mortem examination. In this he was assisted by his son. In his evidence at the inquest, in answer to a question by the coroner, he stated that he could not find any bullet wound in the body. My evidence relating to Lefroy, his reception and treatment at the Brighton Hospital, was next taken, and the coroner then asked me to make an examination of Mr. Gold's body, with a view of finding a gunshot wound. I did so, and Dr. Byass was present at the examination, which was made in the coach-house before mentioned, with closed doors, and a policeman outside to keep the yokels away. The face and body were black with smoke, and much bruised and cut about. After considerable trouble, I found a very small, pinhole wound, a little above the angle of the right jaw. Dirt had settled round the roots of the closely-shaven hairs, so that it was impossible to make out any specks of powder there might be. Dr. Byass did not agree with me as to the causation of the wound, so I cut out a piece of the flesh surrounding the hole and took it away with me. Returning to the inquest room, I stated to the coroner that I had discovered a wound which I thought had been caused by the passage of a bullet. Dr. Byass stated that he did not agree with this opinion. The coroner thereupon asked me to have the skin carefully examined, and, having done so at the hospital the same evening, I informed him by letter that there was no doubt that the wound was gunshot. Next day I took the piece of skin to Scotland-yard, where it was seen by Mr. Bond, who also pronounced the wound as being gunshot. Next day the third examination of Mr. Gold's body was made by Mr. Bond, and I was present and assisted at his request. As he says in his letter to you, the bullet was found lying upon the body of the second cervical vertebra.

Apologising for the length of this communication,

I am, Sirs, yours faithfully,

Liverpool, Dec. 5th, 1887. B. HALL, M.B. Lond.

Dr. Joseph O'Connor.—Relief for the skin irritation in jaundice may usually be obtained by the free use of alkaline lotions, or lotions of carbolic acid, benzoic acid, or borax.

Mr. John J. Weaver.—Raynaud (Maurice): De l'Asphyxie Locale, et de la Gangrene Symétrique des Extrémités (Baillière et Fils, Paris, 1862).

AN APPEAL TO THE PROFESSION ON BEHALF OF H. O. BAYFIELD, L.R.C.P.ED., L.F.P.S.G.

To the Editors of THE LANCET.

SIRS,—On Feb. 26th, 1886, an attempt was made to poison Mr. Bayfield's wife's mother, at that time resident in his house, situated at Lavender-hill, the poison (laudanum) being found in some tea which had just been made. The police were called in, and, after exhaustively questioning the various members of the household, decided of their own action to take the parlour-maid into custody. It was Mr. Bayfield's opinion that they had arrested the wrong servant, and so strongly did he feel this that he not only refused to sign the charge-sheet and to prosecute, but actually instructed a solicitor to watch the case on behalf of the accused. The magistrate, however, sent the case for trial, and the Treasury took up the prosecution; but when the matter came before the Grand Jury the Bill was thrown out. Shortly afterwards the cook confessed that it was she who had poisoned the tea, with laudanum taken from Mr. Bayfield's surgery, her object being to injure her fellow servant. She was tried, and sentenced to three months' imprisonment.

Now comes the point which I am anxious more particularly to bring before your readers. The arrest of the girl originally charged was the spontaneous action of the police, and Mr. Bayfield had nothing to do with it. In spite of this, however, a firm of solicitors took up the girl's case, and brought an action against Mr. Bayfield for £200 damages for false imprisonment. The Treasury declined to act in the matter; so Mr. Bayfield was left to fight the battle alone. The case came on for trial before Mr. Justice Matthew on Nov. 14th, and the jury without leaving the box found a verdict in Mr. Bayfield's favour. Then came in the old story, and the plaintiff having no means, Mr. Bayfield, although victorious, was left to pay his own costs, which amount to £106 on his solicitor's bill alone, to say nothing of the further heavy incidental expenses. Nor is this all; for the sympathy with the girl amongst her own class, who are unable to draw correct inferences from facts, very injuriously affects Mr. Bayfield's position amongst his poorer patients in this locality.

Is not this a case in which the profession may very fairly be asked to assist? Any medical man who dispenses his own medicines might find himself in a similar position at any moment; and a subscription in aid of the costs incurred by Mr. Bayfield in defending himself would have something more than a merely pecuniary value—coming to him as an expression of sympathy from his own profession, it would give him valuable moral support.

Subscriptions will be received by Ed. Bellamy, F.R.C.S., 17, Wimpole-street; R. F. Frazer, L.K.Q.C.P., &c., Lavender-hill; G. Tandy, L.R.C.P.Ed., 43, Cedars-road, Clapham; Joseph Sutcliffe, L.R.C.P.Ed., 511, Wandsworth-road; Fredk. Hunter, L.R.C.P., Haycroft House, Lavender-hill.

The following subscriptions have been received:—John Williams, M.D., £2 2s.; Ed. Bellamy, F.R.C.S., £2 2s.; Henry James, F.R.C.S., £3 3s.

I am, Sirs, yours faithfully,

HENRY JAMES, F.R.C.S.

31, Sisters'-avenue, Clapham-common, S.W., Dec. 5th, 1887.

Dr. McCall (Morecambe).—The members of the Commission were Sir H. Roscoe, Dr. Lauder Brunton, Dr. Burdon Sanderson, Sir James Paget, Dr. Quain, Mr. George Fleming, and Mr. Victor Horsley (secretary).

Mr. Wm. G. Loveridge will find an article on the subject of his question in our Students' Number, published on Sept. 3rd last.

Dr. J. F. Brice.—It is possible that the remedy acts as our correspondent suggests.

"ETHER IN MIDWIFERY PRACTICE."

To the Editors of THE LANCET.

SIRS,—Under the above heading Dr. S. Grose speaks of the good results derived from subcutaneous injections of ether in (I presume) asphyxia neonatorum. I would like to call his attention to an article entitled "A Few Remarks upon Therapeutics," written by me to the *New York Medical Journal*, Aug. 21st, 1886, and which was extensively quoted by medical journals in this country, and an abstract of which, I understand, appeared in Braithwaite's Retrospect. In a division, "The Inhalation of Ether in Non-expansion of Lung, due to adhesions of pleural surfaces, occurring after pleurisy with purulent effusion, in apneumatosis of children, and asphyxia neonatorum," he will find the following recommendations:—"I can also recommend the use of ether in the asphyxia of newly born infants. It will sometimes succeed when artificial respiration fails. A few drops may be placed upon a piece of absorbent cotton and held to the nostrils. A better method is, after the nares have been cleansed of mucus, &c., to insinuate into either nostril a camel-hair brush previously dipped in ether, and, by titillating its mucous membrane, we, in addition, summon to our assistance the benefit of reflex action."

I am, Sirs, yours faithfully,

Wilkes Barre, Pa., Nov. 22nd, 1887. J. HARRIS JONES, L.R.C.P., &c.

VOLUNTARY BOARDERS IN ENGLISH ASYLUMS FOR THE INSANE.

To the Editors of THE LANCET.

SIRS,—Can any of your readers inform the writer if there exists in England any asylum, lunatic hospital, or licensed house in which a person wishing to do so may legally become a voluntary boarder, as in Scotland, with or without the consent of the Commissioners in Lunacy, and without having been at some previous time under certificate of insanity?

I am, Sirs, your obedient servant,

Dec. 5th, 1887. QUÆRENS.

"ROUGH-AND-READY MEDICAMENTS."

To the Editors of THE LANCET.

SIRS,—Adverting to my former contributions on this point, I beg to submit a few more characteristic episodes of this kind, and simply intimating that I will add in connexion with them such explanatory matter only as will suffice for their better elucidation. I will leave them to speak for themselves. They exhibit strong contrasts, from a humanitarian and physiological point of view, with our own more modern as well as more merciful procedures, and they further serve, as I think, to point the moral, even though they do not adorn the tale, of our present therapeutic art and its achievements.

1. Describing the celebrated Cardan's visit to the Bishop of St. Andrew's (Cardinal Beaton?), Randolph, the English Ambassador at the Court of Scotland says ("The History of Scotland," by P. Fraser Tytler, vol. iii., p. 387) that "he [Cardan] practised upon him divers foreign inventions. He hung him certain hours in the day by the heels to cause him to avoid at the mouth what the other ways nature could not expel; he fed him many days with young whelps; he used him sometimes with extreme heats, and as many days with extreme cold."

2. Sir Astley Cooper is reponsible for this story. "A person in this metropolis happened," he says ("Lectures on Surgery," Lond., 1832, p. 73), "to have bow shins. It was a part of his duties to teach ladies to draw and paint, and in the prosecution of this branch of his profession he found his bow shins, as he himself declared to me, a very great evil. He felt that his merits were less fairly appreciated and his instructions less kindly received by reason of the convexity of his shins. He was persuaded, in short, that his bow shins stood between him and his preferment. Under this impression he went to a very noted person in this town, and, showing him his shins, said to him, 'Pray, sir, do you think you can make my legs straight?' 'Sir,' said the doctor, 'I think I can, if you will take a lodging in my neighbourhood. I think I can scrape down your shins and make them as straight as any man's.' A lodging was taken, the father of the patient assisted in the operations, and all three of them—the father, the son, and the doctor—took a turn in scraping down the convex shins. A great deal of rasping was required. An incision of very considerable extent was made in the shin, the integument was turned aside, and an instrument ..... called a rougee was employed to scrape the shin bone..... At last the shell of the bone became so thin, that the doctor said they must proceed no further with that leg. The other leg was then rasped in a similar manner, and thus large wounds were produced in both of the shin bones. The surfaces granulated very kindly, and very little exfoliation of the bones took place, but unluckily the granulations would form bone, so that up-jumped the bones of the shin again. The doctor, however, was not to be defeated, and accordingly put a layer of arsenic over the whole surface. It was in consequence of the effects of this application that I saw the patient. The arsenic was absorbed into the system, and he became paralytic in his arms and lower extremities. A great number of exfoliations took place in his legs, and he showed me a large box of them. I sent him to Bath, where he stayed for some time, and got rid of his paralysis."

3. "The Society islanders had," says Sir J. Lubbock ("Pre-Historic Times," 1st ed., p. 384), "no knowledge of medicine as distinct from witchcraft. ..... When the brain is injured as well as the bone, they have opened the skull, taken out the injured portion of the brain, and, having a pig ready, have killed it, taken out the pig's brains, put them in the man's head, and covered them up." The result does not transpire, but the "treatment" is as simple as it is suggestive, and it is a pity that the missionary, Mr. Ellis, on whose authority he bases it, does not himself testify from personal knowledge to either its soundness or certainty.

I am, Sirs, your obedient servant,

Auriol-road, W., Nov. 28th, 1887. W. CURRAN.

L.K. & Q.C.P.I.—The only consolation we can see in the charges of the unqualified assistant is that they are likely to convey to the poor the best idea of the value of the services offered. As to the questions of etiquette we congratulate our correspondent on his conduct. It is disappointing to find generosity and professional kindness not reciprocated. But that in no degree diminishes the value of such sentiments nor of the conduct which they inspire.

W. Parker, M.B., C.M.—We fear there are no efficient legal means for enabling the removal of such a sign as our correspondent describes.

Horrens.—An article on the subject will be found in THE LANCET of Nov. 20th, 1886.

TREATMENT OF ECZEMA AND PSORIASIS.

To the Editors of THE LANCET.

SIRS,—Having received over 100 letters and post-cards from medical men and patients asking all sorts of questions as to the management and treatment of eczema and psoriasis, kindly give me space to say that I cannot reply to them, that I never prescribe for anyone by post, and that the naphthaline tincture and lotion can be had of Messrs. Schütte and Co., Widmore Quinine Works, Bromley, Kent. The former I have found the best application for very chronic patches of both eczema and psoriasis; I paint it on. The latter I use as a wash in less obstinate cases. I also use Messrs. Schütte and Co.'s dermato-therapeutic quinine lotion in chronic eczema. I have found it by far the best thing I have ever met with for allaying itching and keeping the skin soft.

I am, Sirs, yours faithfully,

Harrogate, Dec. 8th, 1887. A. S. MYRTLE, M.D.

A CENTENARIAN.

To the Editors of THE LANCET.

SIRS,—Through the kindness of a friend I am able to present to the readers of THE LANCET more than a match in longevity to that of Miss Charlotte Pigot, whose history is given by Mr. Ledgard, of Kirkby, Lonsdale, in your impression of Nov. 5th.

The centenarian whom I wish to mention is Mrs. Sirah Markham, at present living at Roxby, a small village about a mile from Winterton, in North Lincolnshire. Mrs. Markham was born on Royal Oak day in 1785. She was one of nine chidren, and when eleven years of age went to service at 14, Old Bond-street, London, where she stayed until she married at the age of twenty-four years. She was left a widow and a mother at the end of nine months, her husband having died from lock-jaw. After her husband's death Mrs. Markham went as foster-mother to a baby who is now eighty years of age, Mrs. Bridgeman Simpson, of Babworth Hall, Notts. Before Mrs. Markham's second marriage she was a nurse in the Sheridan family, and during her service there she frequently saw George IV., who was a constant visitor at the house. She married a second time when she was thirty years of age, and then with her husband settled in Roxby, where she has lived ever since; he, who was seven years her junior, died fifteen years ago. Mrs. Markham had seven children by the second marriage, and has a great many grandchildren and great-grandchildren. She attends church and Holy Communion regularly, can walk very well without the aid of a stick, but does not extend her walks much further than the church, which is not very far from her house. The old lady is only slightly deaf; seven years ago one of her eyes was injured by a stone which was thrown at it, but with the other she can see to read without the aid of spectacles. She is quite upright in figure, and does not look more than eighty years of age, and has a very pleasant face. My informant tells me that she called upon the old lady on Nov. 19th, and was much struck with her wonderful memory. The old lady would go upstairs to fetch a quilt to show her visitor that Lady Francis Simpson had given her on her hundredth birthday. She said she had got up before 7 o'clock that morning, and had blackleaded both her grates, and had washed the floors and done all the housework herself. She lives alone in her cottage, but a grandson sleeps in the house at night. She has always been very abstemious, and has never smoked. Mr. Elwes of Roxby allows her £15 a year, and other friends are very kind to her. She is wonderfully active and self-reliant. A lady a few weeks ago went to Roxby Church, and walking home with the old lady offered her her arm, which, however, the other declined, and walked on in a most independent manner. When she arrived home she unlocked the door, struck a match, and lit the lamp. When her visitor was leaving she told her to be careful and not fall, as the garden path was rather rough, and in order to ensure the visitor's safety she carried the lamp as far as the garden gate to light her down the village. There is an old lady living near who is about eighty-five years of age, and whom Mrs. Markham treats as a baby, and escorts to and from church. On one occasion, when the younger lady had left her spectacles behind her in the church, the elder said to her, "Wait a moment, I will run back and fetch them for you." On a recent occasion, when a lady and gentleman called upon Mrs. Markham, she apologised to them for not showing them into a room where there was a fire, for she had "got the dressmaker in the house.'—Yours truly,

Lincoln, Nov. 29th, 1887. WILLIAM O'NEILL, M.D.

Medicus should inform the person who is acting so remarkably that unless he desists immediately his conduct will be reported to the College from which he holds his diploma, or to the Medical Council. He should also call upon his friend who introduced the *locum tenens* to remonstrate.

Private Practitioner.—We would recommend our correspondent to write to the medical officer of health, and inform him that he will be happy to give information on any point he desires for the purpose of facilitating the performance of his public duties.

Lectures
ON
FIBROID DEGENERATION AND ALLIED LESIONS OF THE HEART, AND THEIR ASSOCIATION WITH DISEASE OF THE CORONARY ARTERIES.

By JOHN LINDSAY STEVEN, M.D.,
ASSISTANT TO THE PROFESSOR OF CLINICAL MEDICINE IN THE UNIVERSITY OF GLASGOW; ASSISTANT PHYSICIAN, GLASGOW ROYAL INFIRMARY; AND ASSISTANT TO THE LECTURER ON PATHOLOGY IN THE WESTERN INFIRMARY OF GLASGOW.

LECTURE II.

DISTRIBUTION OF THE CORONARY ARTERIES OF THE HEART.

As has been gathered from the foregoing considerations, the blood supply of the heart is intimately associated with the causation of the lesions at present under review, and, therefore, before going further it will be necessary briefly to refer to the different views which have been held as to the distribution and anastomosis of the cardiac arteries. Very great differences of opinion still exist as to whether the coronary arteries anastomose or not—some observers holding that the anastomosis between the two vessels is quite abundant and free, others maintaining that it is exceedingly limited or even absent altogether. Amongst the former are to be placed the names of Norman Chevers, Wickham Legg, Samuel West, Krause, and Langer; and amongst the latter those of Hyrtl, Cohnheim, and Joseph Swan. Chevers founds his opinion on a water injection; I think that this is clearly insufficient, and that no reliable conclusion can be drawn from it.[1] Wickham Legg says: "A number of human hearts were collected, and the arteries injected with a blue-coloured size. Nothing was easier than to fill one artery by injecting the other, and communicating branches could be seen passing over the apex of the ventricles....."[2] Samuel West says: "The fact, then, of the very free and complete anastomosis of the coronary arteries is established."[3] It will be admitted that these opinions are most authoritative, and contain the certain convictions of the writers. On the other side of the question, however, the following sentences must be quoted. Joseph Swan says: "Although the coronary arteries communicate at the ring at the base of the heart and at the apex, the communication is not very free; but each can do little more than supply its respective region."[4] Hyrtl seems to have modified his original view that the arteries do not anastomose, and he now admits a capillary anastomosis. Cohnheim held that the arteries were end-arteries, and, with his usual minute care and scrupulous accuracy, has shown that, before coming to any conclusion as to the result of injection experiments, we must take carefully into account the character of the injection fluid used. He found that if a thin fluid, capable of passing easily through the capillaries, were employed, it returned by the opposite artery; but if a thicker fluid, incapable of so passing, were used, it did not.[5] It should be recollected, however, that Cohnheim's experiments were made on dogs, and that, in one of the many canine hearts he examined, he did find a small anastomosing branch. It will be seen, then, that on this question we have on each side a pretty equally balanced consensus of opinion; and, not so much with the hope of finally settling the question as with the object of possibly finding out which side was most likely to be right, I undertook a few injection experiments of the human heart, of which the following is an account. I made in all three careful arterial injections of healthy human hearts, after which they were examined and dissected, and the conditions found were noted at length at the time of experiment or of examination.

Injection 1.—This experiment was carried out on Jan. 17th, 1885; the fluid used was the ordinary histological carmine gelatine mixture, the continuous pressure apparatus being employed, and a maximum pressure of from eight to nine centimetres of mercury was used. The vessels before injection were washed out with salt solution; the mass was thrown into the left coronary artery, and after a short time it flowed from the right coronary in an oozing fashion. The tissue of the left ventricle and auricle was fully injected, but that of the septum and right side scarcely at all. By tracing out some of the branches it became obvious that the main point of communication between the two vessels had been in the apical region.

Injection 2.—In this case an exceedingly careful anatomical injection of both arteries was made, in order that by subsequent examination and dissection any anastomosing branches might be discovered. In this and the succeeding injection, I had the valuable assistance of my friend Mr. A. E. Maylard, B.S. Lond., formerly of Guy's Hospital, and the method employed was that of Mr. H. G. Howse, described in Guy's Hospital Reports. The glycerine and arsenic preserving fluid was thrown into both vessels by the constant pressure apparatus at a pressure of eight centimetres of mercury, and it was particularly noted that there was no return by either artery during the process. The glycerine fluid was of the consistence of mucus. On the following day red lead mixture was thrown into both vessels by a powerful anatomical injection syringe. The vessels to their minutest ramifications filled out well, but there was no return by either artery. A careful dissection was made, and full notes of all the appearances observed were kept. Between the two coronary arteries three very fine and delicate anastomosing branches were discovered, all of them, however, so exceedingly small that a lens was required to trace them—viz.: (1) between the transverse branches on the posterior surface of the auricular ventricular sulcus there were two hair-like connecting vessels; (2) one hair-like vessel passed behind the aorta to connect the auricular branches; (3) a branch connecting the two vessels, which was verified by a lens, was found near the apex on the surface of the right ventricle. Between branches of the same artery only two very small anastomosing vessels were discovered, and both were in connexion with the left coronary. Not one of these connecting branches deserves to be considered as much more than a capillary branch, and had there been any larger communicating vessels it is not easy to see how they could have escaped detection.

Injection 3.—Both vessels were filled with glycerine solution under a pressure of from five to eight centimetres of mercury. The red paint solution was then thrown into the right coronary; the vessel filled out to its smallest branch. A careful dissection failed to find any communicating branch, although there must have been one or two small anastomoses, as in one of the descending branches of the left coronary a minute fragment of the red injection mass was found; and at the time of the glycerine injection one branch of the right coronary was found to be slightly filled while the left was being injected.

I think, therefore, it must be admitted that inosculations do exist between the coronary arteries of the heart, but that these are anything like so large and numerous or of so much importance in maintaining the vitality of the heart when a branch is plugged, as one would gather from the statements of Wickham Legg and West, is, I think, much to be doubted. So far as my experience goes, I would say that the arterial inosculations are so trifling and so far apart from one another that they are quite unable to compensate for vascular obstructions, except in their immediate neighbourhood, and even there only after very considerable destruction of cardiac tissue has occurred. To be of any service in the way of restoring circulation after obstruction the anastomoses would need to take place through the medium of primary and secondary branches, and Strathers has pointed out that Hyrtl only said that the coronary arteries did not anastomose by such branches, a statement with which I perfectly agree. In two of the cases of obstruction of the coronary arteries to be afterwards recorded an injection of soluble Prussian blue was made by Dr. Joseph Coats in order to throw light upon the question of anastomosis. It was seen that the communication between the two vessels was pretty free, but, taken by itself and in the

Digitized by Google

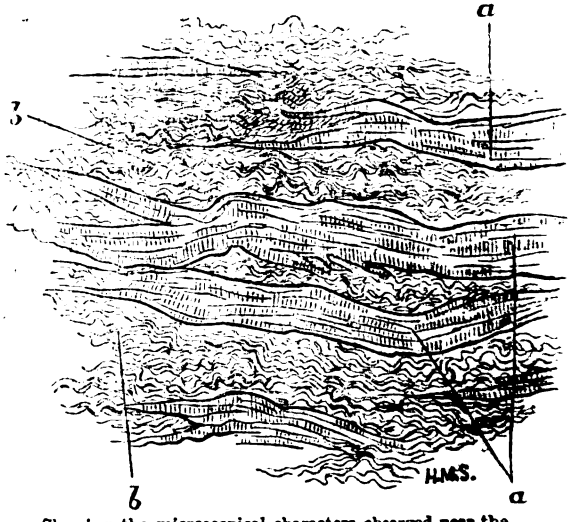
absence of any careful dissection, such an experiment would only prove a capillary, or, if we may so speak, an *arteriolar* anastomosis, the existence of which, I think, must be admitted, but the service of which in compensating for any serious obstruction may fairly enough be doubted.

LESIONS OF THE HEART-WALL, WHICH MAY BE ASSOCIATED WITH DISEASE OF THE CORONARY ARTERIES.

The lesions of the cardiac muscle which are most likely to result from obstructed coronary circulation are—(1) *Fibroid Degeneration;* (2) *Fatty Degeneration;* (3) *Infarction of the Heart,* associated not uncommonly with spontaneous rupture of the ventricular wall. The lesions have been named in what I think to be the order of their frequency and importance, but for certain etiological reasons, which will become apparent afterwards, I prefer, in considering them in detail, to place Fatty Degeneration last. These morbid states, though very frequently occurring quite independently of each other, may be combined in the same heart, as is illustrated by some of the cases to be afterwards recorded.

Fibroid Degeneration.

In the course of the critical review which I have given of the literature of this affection it has been shown that in the minds of most English observers fibroid degeneration and chronic inflammatory change of the myocardium are regarded as practically synonymous terms (at least so it is stated by Bramwell). That this is not so, it is, as I have already said, one of the purposes of these lectures to prove. In a very large number of cases fibroid change is associated with disease of the coronary arteries of the heart, and if this be so then we have to deal with an affection of the myocardium, which may logically be placed in a category *per se*, and which clinically and pathologically has as much right to be regarded as nosologically a separate and distinct affection of the heart as, let us say, fatty heart. We have, I believe, in fibroid degeneration of the heart a morbid condition, the possibility of the presence of which should always be borne in mind by the careful clinical observer as a frequent source of cardiac weakness, and even of fatal syncope.



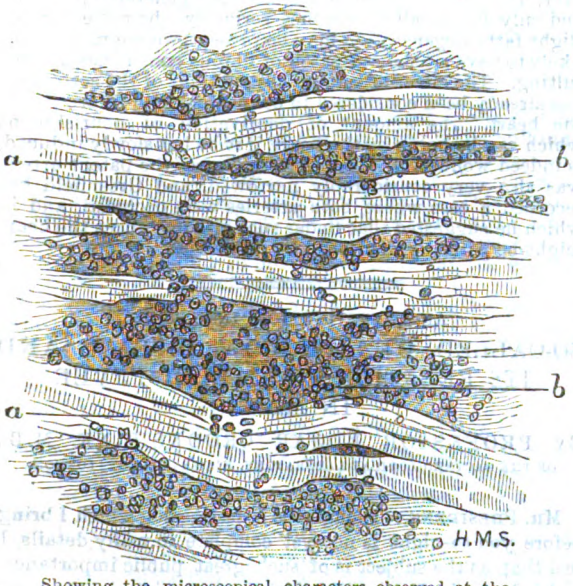
Fibroid degeneration is generally found in the wall of the left ventricle, and the extent of the affection may vary within very wide limits. Thus in some cases we may not find more than a patch or two the size of a split-pea or an almond, or, on the contrary, we may find the entire thickness of a very considerable area of the ventricular wall converted into a dense white fibrous tissue, as is perhaps most strikingly seen in cases of aneurysm of the heart. It is not at all infrequent to find the musculi papillares converted into tough fibrous tissue, and in some cases this may be the starting-point of the disease as regards other regions of the myocardium. In cases where the muscular tissue is extensively changed, as in cardiac aneurysm or fibroid disease affecting the entire thickness of the ventricular wall (see Cases 9 and 10 of the series to be afterwards given), there is not the slightest difficulty in at once recognising the morbid state.

In a very large number of the slighter cases, however, unless the lesion is carefully searched for it is almost certain to be overlooked, and under these circumstances it is only after slicing through the muscle in sections parallel to the surface that the morbid state can be detected. When thus present and discovered in the substance of the muscular tissue, fibroid degeneration presents the following naked-eye characters, which are typical and easily recognised. It occurs as a bright, white, glistening patch of irregular size and shape, and of tendinous character; the cut surface of the patch is usually depressed below the level of the surrounding muscle, and has a streaky, fibrous appearance, the fibres running in the direction of the normal muscular bundles. There is no sharply defined line of demarcation between the healthy and the diseased tissue, the normal passing into the abnormal quite irregularly. These are the appearances as described by Huber, by whom, at Leipzig, my attention was first drawn to the subject, and they are those which I have always seen in cases which I have since examined in this country.

When examined under the microscope the patch is found to be entirely composed of delicate wavy fibrous tissue, often presenting a very finely granular appearance. In well-marked cases—i.e., of fibroid degeneration as distinguished from chronic interstitial myocarditis—no cellular infiltration is to be seen, nor anything in the least suggestive of inflammatory action. The margin of the patch is quite irregular, and the adjoining muscular bundles are more or less broken up and separated from one another by encroachment of the fibroid metamorphosis. The separated muscular fibres at the extremity of the patch are usually pointed, and often become finer and finer until the fibre is lost in the fibroid tissue. Sometimes the muscle-cell seems to be prolonged into a wavy fibre, an appearance very suggestive of the gradual wasting of true muscle substance, only the connective tissue remaining to form part of the morbid area. It is also frequently seen that the muscular fibre itself has a wavy character very similar to that presented by the strands of fibrous tissue. In the midst of the patches isolated and much atrophied muscular fibres are frequently seen, and all the appearances evidently point to a gradual loss of true muscle substance, and to its place being taken by the wavy fibrous tissue. (See Fig. 1.) Minute arterial branches may often be made out in or in the neighbourhood of the patches, and these often give evidence of not being strictly normal, the chief abnormalities observed being a very decided hypertrophy of the muscular coat, and sometimes perhaps a slight thickening of the internal.

Etiological considerations.—In the foregoing remarks enough has been said to indicate pretty clearly my decided opinion that in true fibroid disease (perhaps it might be more correctly termed, as I have already pointed out, fibrous transformation) of the heart we have to deal with an

FIG. 1.



Showing the microscopical characters observed near the margin of a patch of fibroid degeneration. (Zeiss D. Eye-piece No. 3. × 350.) The drawing was made from a section taken from Case 3. *a*, Muscular fibres. *b*, Wavy fibrous tissue.

atrophic process going on in the affected areas, and that this atrophy is directly to be related, in the great majority of cases, to a diseased condition of, and consequent insufficient nutrient supply from, the coronary arteries. Of the very frequent association of fibroid degeneration with diseased or obstructed coronary arteries, the cases given by Huber, and also those to be afterwards recorded in the appendix, leave, I think, no very reasonable doubt. There is also but little difficulty in understanding the relationship existing between the two conditions and in tracing the sequence of events. Owing to the gradual obliteration of a particular branch of the diseased artery, and to the difficulty of establishing collateral circulation, a certain area of muscular tissue is slowly deprived of its necessary blood supply. Under these circumstances the connective tissue, requiring less nourishment and more tenacious of life than the muscle substance, is able to subsist on the diminished nutrient supply, whilst the more delicately and highly organised muscle readily succumbs. The muscular fibres slowly atrophy and disappear, and a fibroid patch is left. The patchy character of the disease is due, I believe, to the fact that all the branches of the coronary artery are not equally affected or obstructed. Fibroid degeneration is thus, in the first instance at least, always a localised affection, and never involves the entire myocardium simultaneously, although neighbouring patches may coalesce, and so give rise to extensive areas. It may

Digitized by Google

be associated with fatty degeneration, which, though patchy or mottled in distribution, is generalised and dependent, as I shall endeavour to show, on a general as distinguished from a local deprivation of blood supply. In cases where the arteries are apparently healthy to the naked eye, abnormalities may be discovered with the microscope (see Cases 2 and 3); and in cases where the arteries are actually healthy, branches may be obstructed by emboli, and give rise to the affection in the manner soon to be adverted to (see Cases 4 and 5). Fibroid degeneration of the heart is, I believe, most frequently caused in the manner already described; but there can be no doubt that in a certain proportion of cases we may have fibrous patches in the myocardium which are inflammatory in origin—i.e., we may have a true interstitial myocarditis as opposed to a true atrophic fibroid degeneration.. Case 10 seems to be an illustration of this form of disease. In many cases associated with pericardial adhesions the origin of the affection is inflammatory, and probably an extension from the inflamed serous membrane. In such cases numerous leucocytes are found mingled with the fibrous tissue and lying between the muscular fibres, a condition of matters which is hardly ever found in pure atrophic fibroid degeneration. In cases of syphilis, too, fibroid patches, which have probably resulted from the presence of gummata, have been found in the heart wall; and

FIG. 2.

Showing the microscopical characters observed at the margin of a patch of interstitial myocarditis. (Zeiss D. Eye-piece No. 3. × 350.) The drawing was made from a section taken from Case 10. *a*, Muscular fibres. *b*, Leucocytes and new fibrous tissue.

in Case 10 there was also evidence, especially in the condition of the liver, that the patient had suffered from that disease. In this regard a case of syphilitic disease of the heart reported by Mannino, which had been under the care of L. Federici, is of some interest.[6] Under such circumstances, the development of fibrous tissue in the myocardium obeys the laws which regulate inflammatory new formations in general. To such cases only can the term "interstitial myocarditis" be logically applied. (See Fig. 2.)

Clinical suggestions.—With regard to the clinical aspects of fibroid degeneration of the heart it is much more difficult to speak in definite terms. There is no definite physical sign, so far as I know, by which we can diagnose its presence, and at best we can only surmise its existence by taking a comprehensive view of the whole pathology of the case. As has been seen, it constitutes a very distinct and easily recognised lesion of the cardiac wall, and as such the possibility of its occurrence should always be kept in mind by the careful physician; and this is all the more necessary when we reflect that, if the lesion is at all extensive, it may be a powerful factor in producing cardiac debility, and under certain circumstances, as Fagge and Huber have shown, it may lead to sudden death. In all cases of widespread disease of the arterial system (arterio-sclerosis of the Germans), of cardiac dilatation, and of valvular disease arising in middle life apart from the rheumatic diathesis, the possible influence of fibroid degeneration as one factor in the production of the symptoms should be borne in mind. The symptoms may probably be very similar to those usually ascribed to fatty heart, and I think it not at all unlikely that a number of cases likely to be set down as examples of this affection may be fibroid. Further than this I feel I cannot at present venture to go with regard to the clinical significance of this lesion, as so far my studies with regard to it have been pursued in the post-mortem room, and not at the bedside. I have, however, since the present investigation was undertaken, seen a considerable number of cases in hospital practice in which I strongly suspected the presence of fibroid degeneration, and, if clinical opportunities accumulate, these may perhaps at some future time be recorded in this connexion. With regard to the generalised form of the disease described by Dr. Charlewood Turner[7] I can at present say nothing, as I have hitherto had no experience of it, and no opportunity of examining it. There is only one symptom which should be specially mentioned in connexion with fibroid degeneration, and that is angina pectoris. The association between this and a morbid state of the coronary arteries has been pointed out long ago, and in many of my own cases angina pectoris was a prominent and most distressing symptom.

Infarction of the Heart Wall.

This is a lesion which is to be directly associated with a morbid condition of the coronary arteries, and which very frequently leads to spontaneous rupture of the ventricular wall. The naked-eye appearances of acute cardiac infarction (myomylacia cordis of Ziegler) are sufficiently striking. The area may vary very considerably in size, and the affected tissue is as a rule much softened. In the recent state, when cut into, it presents a brown colour, and its surface is depressed below the level of the surrounding tissue; in severe cases the affected part may be semi-fluid in consistence. The microscopic appearances have been described at length by several observers, and as I shall advert to them afterwards in briefly describing typical cases (see Cases 4 and 5), it is unnecessary to refer to them in detail in this place. The muscular tissue is more or less broken up, and in many places has undergone coagulation necrosis—the nuclei and transverse striæ having disappeared, and the fibres having assumed a glassy homogeneous appearance; there is often a dense infiltration of round cells, probably from inflammatory reaction; the neighbouring bloodvessels are liable to be engorged with blood; and red blood-corpuscles are usually discovered in large numbers lying in the interstices of the tissue.

Etiological and clinical considerations.—Acute softening of the myocardium is almost invariably caused by complete and sudden occlusion of the arterial branch supplying the affected area of the heart-wall. The size of the area and the liability to subsequent rupture are directly dependent upon the size of the obstructed branch, as is illustrated by the cases of rupture recorded in the appendix. As a general rule, cases of infarction leading to rupture are associated with extensive disease of the coronary arteries, where, in addition to the chronic deterioration of nutrient supply, a sudden obliteration of the arterial trunk has occurred—e.g., by the sudden occurrence of thrombosis or embolism. But besides this very serious form of infarction there is also a variety of the affection (illustrated by Cases 4 and 5) in which the occluded vessels are small, and in which the resulting infarctions are also small and may be multiple; and it is necessary before going further that this form of lesion should be referred to at some length. Cases 4 and 5 are good examples of this condition, and a description of the appearances usually present will be given in describing them afterwards. Here also, just as in the slighter varieties of fibroid disease, the lesion, unless specially searched for, may be altogether overlooked, because there may be nothing either on the endocardial or pericardial surface to indicate its presence. In this condition the walls of the coronary arteries may be perfectly healthy, and probably the most frequent cause, as seen in Case 4, is severe endocarditis with abundant loose vegeta-

[7] Loc. cit.

Digitized by Google

tions of the aortic curtains, giving rise to multiple embolism of the coronary branches. It was once believed that the mouths of the coronary arteries were closed by the aortic curtains flapping against them, and that the arteries were filled by the recoil of the blood after the systole was over and the curtains closed. We are, however, indebted to several observers for showing that the orifices of these vessels are open during the systole, and that the coronaries of the heart receive their blood-supply precisely like the other arteries of the body. Chief among these observers must be mentioned the names of Martin and Sedgwick,[8] and of Worm Müller and Sandborg.[9] There is thus not the slightest difficulty in understanding how under such circumstances embolism of the coronary arteries should be a not infrequent occurrence, and I think it not unlikely that we have in this morbid state a cause of cardiac debility and failure in severe aortic disease, and in other diseases of the heart as well, which has hitherto been overlooked on the part of clinical observers. Embolic lesions of this kind, small and multiple as they are, are not very likely ever to cause rupture of the organ; but it is quite possible to conceive the likelihood of a large embolic occlusion suddenly leading to this fatal result. Such a lesion, too, might be suddenly fatal without rupture, and before any very serious change in naked-eye appearance of the myocardium had been produced; for Cohnheim[10] and others have shown, in the case of dogs, that occlusion of a large coronary branch leads to stoppage of the heart in from thirty seconds to a minute. Minute and multiple embolic lesions, however, may be regarded as intermediate between the slowly progressing and localised atrophy leading to fibroid degeneration, and the sudden suspension of vitality over a large area, terminating in sudden death or spontaneous rupture. In Case 4 I think I have direct evidence of the truth of this statement. In this case, in addition to the small, soft, brown infarctions, there were also numerous minute areas of fibroid degeneration—the explanation of this doubtless being that, after the degenerated muscular substance had been absorbed, a fibrous patch, practically a scar, remained behind. The clinical importance of a morbid process of this kind directly resulting from valvular disease of the heart can hardly, I think, be over-estimated. With regard to the subject of rupture of the heart and its association with obstruction of the coronary arteries it is unnecessary for me now to speak, because I have elsewhere fully discussed the question in all its bearings.[11] Among the cases to be recorded as illustrating the present remarks, three of spontaneous rupture, in which the dependence of the accident on an obstructed coronary branch was undoubted, will be found, and in connexion with these is described all that is necessary to be said with regard to the histology and pathological anatomy of the condition.

Fatty Degeneration.

Fatty degeneration of the heart may frequently be directly associated with a diseased condition of the coronary arteries, although, as is well known, there are very many other morbid states which may give rise to it. In the present connexion it is well to bear in mind the distinction between fatty infiltration and fatty degeneration of the heart. In the former we have, practically, merely an exaggeration of the normal adipose tissue of the organ, in which the muscular bundles are pushed asunder, and caused to atrophy by the growth of the fatty tissue (fatty growth on the heart). In the latter we have a real conversion of the true muscle substance into fat, granular molecules of fat making their appearance in the muscle-cells, first of all in the neighbourhood of the nucleus, and ultimately filling up the whole cell. It is of the latter of the two conditions only that I am now speaking, as I have no evidence to show, nor have I seen it stated, that fatty infiltration of the heart is in any special way connected with disease of the coronary arteries. Fatty degeneration presents itself as yellow flecking or mottling, visible to the naked eye, on the endocardial surface, and generally most typically seen in the left ventricle. It is chiefly, if not solely, caused by any serious deterioration either in quantity or quality of the blood; thus it is almost a necessary concomitant of all profound anæmias, and, as showing the influence of deteriorated quality of the vital fluid, it is also found in connexion with certain forms of poisoning, a circumstance which has been frequently put to the test of experiment. This being so, one does not wonder that fatty degeneration should be frequently met with in cases of disease and obstruction of the coronary arteries, from the organ being thus deprived of its necessary nutrient supply. In several of the cases which form the basis of these remarks fatty degeneration was found along with the fibroid disease, but the fatty change was specially typical in the last two cases of the series—i.e., those in which a whole coronary artery was shut off from its blood supply by reason of complete obstruction at its point of origin. In Case 15 the generalised fatty degeneration was so pronounced as to produce a more than usually prominent naked-eye change; and there can be no doubt that the very serious interference with the coronary blood supply in these two cases was entirely to blame for the widespread fatty change in the muscular fibre. From what I have seen I would be inclined to formulate the following proposition, subject of course to the corroboration to be afforded by more extended observations—viz., in all cases where the main coronary trunk is slowly obstructed, and at last completely occluded at its origin, a generalised fatty degeneration is likely to result, and the cause of this change is essentially similar to that operative in profound general anæmias or phosphorus poisoning—viz., a grave deterioration of the blood supply to the whole organ. When, however, the arteries, though diseased, are generally pervious, and only the smaller branches seriously obstructed, while slight fatty degeneration may be present, we are much more likely to have a localised patch of fibrous transformation resulting. The effect of sudden obstructions of the coronaries has already been considered in connexion with infarction of the heart. The amount of deprivation of nourishment which can be borne by the heart, if it be but slowly induced, is indeed wonderful. In two of my cases the patent artery was also very considerably narrowed, and Greenfield has recorded a case where both arteries were occluded, and in which he suggested that under such circumstances the heart might be partially nourished by imbibition.[12]

AN INVESTIGATION INTO THE

SO-CALLED HENDON COW DISEASE AND ITS RELATION TO SCARLET FEVER IN MAN.[1]

BY PROFESSOR EDGAR CROOKSHANK, M.B.,
OF THE BACTERIOLOGICAL LABORATORY, KING'S COLLEGE, LONDON.

MR. PRESIDENT,—Though the investigation which I bring before you to-night is not yet complete in many details, I feel that, as the subject is of such great public importance, and information is awaited with keen anxiety in the agricultural world, it is right that an account of what has so far been done should at once be published, especially as the evidence which has already come to hand has forced me to come to definite conclusions. I would add I feel strongly in investigations which are so strictly pathological that the assembly to whom the results should first be made known is this Society. I desire, therefore, most cordially to express my indebtedness to Professor Brown of the Agricultural Department of the Privy Council for giving me permission to lay this matter before you, and to you, Sir, for having enabled me to do so without any delay.

Origin of the investigation.—I will ask you first of all, Sir, to allow me to remind you of the circumstances which have led to a searching inquiry being instituted by the Agricultural Department of the Privy Council into a disease in cows and its relation to scarlatina in man.

Scarlatina in Marylebone.—On Dec. 18th, 1885, Mr. Wynter Blyth reported to the Local Government Board a sudden and extensive outbreak of scarlatina which was associated with the distribution of milk by a particular retailer in South

[1] Abstract of a Report to the Agricultural Department of the Privy Council, read before a special meeting of the Pathological Society of London, Dec. 15th, 1887.

Digitized by Google

Marylebone. The retailer procured his milk from two farms, and there can be little doubt that the milk responsible for the outbreak was derived from a certain dairy farm in Hendon. Mr. Blyth and the medical officer of health for Hendon, Dr. Cameron, were unable to obtain any clue as to the source of infection, and Mr. Power was deputed by the Local Government Board to make an inquiry into the matter.

Mr. Power's diagnosis.—Mr. Power, having come to the conclusion that the milk had not become infected from any human source, proceeded to investigate the condition of the cows. A careful examination was made with a view to detecting any disease among the cows, and it was discovered that there were several on the farm which were suffering from a disease characterised by the appearance of vesicles and ulcers on the teats and udders. At this stage Dr. Klein became associated with Mr. Power in the inquiry, and we are told that their belief in the existence of a constitutional disease among the cows on the farm capable of producing scarlatina among human consumers of the cows' milk became unreserved. Dr. Klein took with him samples of milk, contents of vesicles, and discharges from ulcers, and afterwards two cows were purchased and conveyed to the Brown Institution. At this stage of the inquiry a cowman pointed out to Dr. Klein that he had seen the disease on a certain cow which was one of a batch that had been imported on Nov. 15th from Derbyshire.

Dr. Cameron's account.—In a paper read before the Epidemiological Society, Dr. Cameron gave a detailed description of this cow disease. He pointed out that it was a specific contagious and infectious disease, capable of being communicated to healthy cows by direct inoculation of the teats with virus conveyed by the milker from a diseased animal. Further, he pointed out that the disease was communicable to man.

The disease in man.—A trusty informant received the virus into a recent scratch on the forefinger while milking a diseased cow. General weakness, malaise, and loss of appetite resulted, and after about four or five days a vesicle or small blister appeared on the finger. This broke, and several others formed on the back of the hand. The whole hand and fingers became swollen and inflamed, the inflammation extending in broad lines as far as the elbow. The general disturbance lasted a fortnight.

Symptoms in the cow.—Dr. Cameron regarded the disease in the cow as constitutional, and he pointed out the occurrence of initiatory fever, cough, sore-throat in severe cases, discharges from the nostrils and eyes, eruption on the skin round the eyes and on the hind quarters, vesicles on the teats and udders, and visceral lesions.

Character of the eruption.—The condition of the teats is described as follows:—The teats became enlarged, swollen to nearly twice their natural size, and œdematous. On fingering them there was no feeling of induration. Vesicles or bullæ then appeared on the swollen teats and upon the udder between or near the teats. These varied in number from two to four on a teat, and in size from a pea to a horse-bean. The vesicle contained a clear fluid. The vesicle, Dr. Cameron adds, was not preceded by a hardened papule, but was in the first instance a vesicle or bulla. The vesicles were rubbed and broken on milking, and left raw sores, sometimes red, in other cases pale in colour, with raised ulcerated edges. Sometimes a few accessory vesicles formed around the margin of these ulcerated sores. After the rupture of the vesicle a brown scab formed, which might remain attached for five or six weeks or fall off in ten days or a fortnight, a smaller one forming afterwards. A thin watery fluid exuded from under the scab and the sore ultimately healed. Many scabs varied in size from a shilling to a florin; they were about one-eighth of an inch thick in the centre, thinning off towards the edges. When picked off, the recently healed skin was of a pearly-blue colour, with slight tendency to bleed when the scabs were forcibly detached. According to Dr. Cameron there was no depression of the vesicle or pitting of the skin. The swelling of the teat gradually subsided.

Dr. Cameron's diagnosis from cow-pox.—Dr. Cameron thus sums up the diagnosis from cow-pox: "No hard pimple preceding vesiculation, no subsequent formation of pustule, no central depression of the vesicle, no marginal induration, no areola, and no pitting." In connexion with this, it should be observed that Dr. Cameron acknowledges that not all of his account had been the result of personal observation, and that of necessity some of the earlier symptoms had been learnt from other persons.

Dr. Klein's account.—I will now follow with the account given by Dr. Klein. He states that on the teats and udders of two cows which he investigated there were several flat irregular ulcers, varying in diameter from a quarter to three-quarters of an inch. Some ulcers were more or less circular, others extended in a longitudinal direction on the teat. The ulcers were covered with a brownish or reddish-brown scab. The margin of the ulcer was not raised, nor was there any perceptible redness of the skin around. A small vesicle would make its appearance on a greatly swollen teat, and in the course of a couple of days assume the character of the above ulcers. As a rule, the disease affected the teats; but in some there was also, on the lower part of the udder here and there, an ulcer. In such animals patches denuded of hair were noticed on various parts of the skin, the tail and back particularly. In these patches the epidermis was scaly and the cutis more or less thickened. The animals looked thin, but not strikingly so. In feeding capacity, milking power, and body temperature there was nothing abnormal. Two of these animals, as I have already mentioned, were sent to the Brown Institution.

Post-mortem appearances.—Both were killed, and at the necropsy there were found on one (No. 3) petechiæ under the pulmonary pleura, peripheral lobules congested, and adhesions between lower lobes of lung and costal pleura; in the liver reddish streaks and patches; spleen and kidneys slightly congested; on the placenta petechiæ. In the other (No. 4) there were numerous congested lobules in the lungs, and pleural adhesions; cortex of kidneys congested.

Inoculation experiments.—To study the transmissibility of the disease, Dr. Klein inoculated four calves in the corium of the groin and the inside of the ear with scrapings from the ulcers after removal of the crusts. In calf No. 3 there was vesiculation at the margin of the spot inoculated, and in the centre commencing formation of a crust. On the seventh day each sore on the ear had enlarged to about half an inch in breadth, and was covered in its whole extent by a brownish crust. On the eighteenth day they had all healed up and become converted into flat scars.

The micrococcus of scarlatina.—To search for micro-organisms, Dr. Klein removed the crust from an ulcer on the teat, scraped off the most superficial layer, squeezed the ulcer, and made cover-glass preparations with the exuded lymph. Tubes of nutrient gelatine and nutrient agar-agar were also inoculated. Dr. Klein succeeded in isolating a micrococcus which, after three to six days at 20° C., formed at the line of inoculation small points or granules, whitish in colour and tolerably closely placed. In the depth of gelatine the channel of inoculation was visible as a whitish streak, made up of smaller and larger droplets. The gelatine was not liquefied. Cultivated in milk and incubated for two days at 35° C., the milk was turned solid. Microscopic examination of a culture showed that there were micrococci, diplococci, and shorter and longer chains. In both, after two or more weeks' incubation, very long chains were formed. The micrococci showed a peculiar mode of division. The chains showed branchings, and here and there in a chain the presence of a larger element amongst the smaller ones.

Inoculation with cultivations.—Dr. Klein inoculated two calves in the groin with the cultivated micro-organisms. One calf died in twenty-seven days. No ulcers resulted, as after inoculation with the scraping of the sores; but at the necropsy there were found peritonitis, hæmorrhagic spots on the omentum, congested liver, kidneys, and lungs, petechiæ under the pleura, and pericarditis. In the second calf, on the nostrils and lips and in the hard palate and gums numerous irregularly outlined patches were seen. They were discoloured, brownish, with a very slightly raised margin and a paler centre. This animal was killed, and at the necropsy there were congested lungs, kidneys, and hæmorrhagic patches on the spleen. Thus in neither of these cases was a real ulcer produced as the result of the inoculation of the cultivated organism, but the post-mortem appearances and anatomical features recalled to Dr. Klein the lesions of scarlatina. In the kidney, for example, there were congestion of the cortex, hæmorrhages and glomerulo-nephritis, and granular or opaque swelling of the epithelial cells and infiltration with round cells. From the blood of the heart the micrococcus which had been used in the inoculation was recovered. In view of the evidence, Dr. Klein concluded that the *streptococcus was identical with the virus of the cow disease*, and that it produced a disease very closely resembling that of scarlatina. In a paper read before the Royal Society, Dr. Klein describes how the work was carried on during 1886-87. Dr. Klein

Digitized by Google

found in the blood of human scarlatina that a micrococcus was present in four out of eleven cases. The micrococcus proved to be identical in its microscopical appearances and in its characters on cultivation with the micrococcus found in the Hendon cow disease. And by inoculation with a cultivation of the scarlatina micrococcus, he states that a cutaneous and vesical disease resulted, which was identical with that produced in the calves infected with the micrococcus from the Hendon cows.

Dr. Klein's conclusion.—In conclusion, Dr. Klein says:—"It must be evident from these observations that the danger of scarlatinal infection from the disease in the cow is real, and that towards the study and careful supervision of this cow disease all efforts ought to be directed *to check the spread of scarlet fever in man.*"

An eruptive disease is reported.—Cases of an eruptive disease of the cow having been reported to the Agricultural Department of the Privy Council, I received instructions from Professor Brown to undertake a series of researches on the lines indicated by Dr. Klein. The first animal that came under my observation had been purchased and removed to the Royal Veterinary College. This cow I shall speak of as No. 1. She was fairly well nourished, eat well, and was normal in her milk supply. Her temperature was normal on admission, but subsequently rose from mammitis occurring as a complication. There was no desquamation, nor were there in this case any patches destitute of hair.

Character of the eruption.—But there was a characteristic disease of the udder and teats. On the right teats there were numerous sores varying in size from a pea to a penny. The sores were covered with crusts varying in thickness and generally fissured. In some they were flat, in others conical. Some were with difficulty removed with forceps, others were readily detached. The crusts varied in colour from reddish-brown to a very dark brown or almost black. On detaching or scraping a crust there was a granulating and somewhat indurated base. On the right anterior teat there were several ulcers, from which apparently the thick crusts had been detached, and new scabs were forming. On the left posterior teat there were unusually large dark-brown crusts, especially at the extremity of the teat.

Examination for micro-organisms.—Having entirely removed the crusts from some of these ulcers, I squeezed the base, and from the discharge I made a number of inoculations in nutrient gelatine and nutrient agar-agar. I also collected the discharge in capillary tubes and sealed them immediately, and also made a number of cover-glass preparations.

Inoculation experiments.—With the discharge and with scraping from the ulcers I inoculated four white mice, one guinea-pig, and two calves. Of the two calves one was inoculated by scarification on both ears; the other was scarified on the left ear and inoculated on the left groin by making an incision through the corium and rubbing in a scraping from an ulcer. In each ear and in the groin there were positive results. In the large brown calf inoculated in the right ear in two places, one place went through the following changes. On the third day there was apparent vesiculation, and commencing formation of crust. From day to day the crust thickened, and on the eighth day the crust was at its height, and detached at the edges. By removing the scab an ulcer was exposed. There was slight inflammatory thickening. About the thirteenth day the ulcer had quite healed. This corresponds very closely with the results obtained by Dr. Klein. The temperature of the calf was only slightly raised.

Cultivation experiments.—I will now describe the result of the cultivations. The inoculations had been made for the most part in tubes of nutrient gelatine and nutrient agar-agar solidified obliquely. To separate the different organisms that might be present, I employed either Koch's plate-cultivations or Esmarch's method, or I simply drew the platinum needle in a line on the surface of the nutrient medium. Agar-agar tubes, inoculated in this way, were placed in the incubator at 37° C., and gelatine tubes were kept at 20° C. In the course of two or three days a growth commenced along the track of the needle, consisting mostly of china white, yellow, orange, and little dot-like colonies. Examination of the latter with a magnifying glass showed a little darkened centre corresponding exactly with the figure given by Dr. Klein. Cover-glass preparations revealed at once an organism identical in form with that described by Dr. Klein. From these colonies cultivations were established in a number of tubes of nutrient gelatine, and in two or three days, at 20° C., the cultivations gave the peculiar finely dotted appearance which has been figured and described so minutely. These preparations were demonstrated to Professor Brown on Nov. 23rd. This micrococcus grows also in broth and turns milk solid, so that it exactly corresponds with the description and figures given by Dr. Klein of the so-called *micrococcus scarlatinæ*. As I had procured cultivations, the animal was ready to be killed, and Professor Brown was anxious that Dr. Klein should be present at the post-mortem. In deference to Dr. Klein's wishes the cow was conveyed to the Brown Institution, on the condition that due notice was given to enable us to be present at the necropsy.

Another outbreak.—On Nov. 24th I accompanied Professor Brown to see another cow affected with a similar disease belonging to a herd in another county. The affection in this case was not so severe, but it also showed the same characteristic brown or reddish-brown crusts, which on removal exposed a granulating thickened base with exudation of a lymph-like discharge and slight hæmorrhage.

Natural infection.—The cow was suckling a calf, and this calf had previously been suckled by another cow also affected with the same eruption of the udders and teats. The calf had developed flat angry-looking ulcers on the nose and hard palate, and an eruption in the hairy part of the nose near the muco-cutaneous line of union. Cow No. 1 having been sent to the Brown Institution, a second cow (No. 2) was purchased from the same herd as No. 1. This cow also had a calf with suspicious places on each nostril: on the right side an apparent abrasion, and on the left a distinct but thin flat brownish scab. It would appear, then, that these calves had inoculated themselves by sucking the sore teats.

Inspection of an infected herd.—On Saturday, Nov. 26th, I proceeded to the affected farm from which the diseased cows Nos. 1 and 2 had been purchased. On my arrival I made inquiries as to the first occurrence of the outbreak. I gathered that it appeared about the end of September, but it was said that no fresh cows were imported at that time. The disease commenced at a farm which I shall call V. The cows were moved from farm to farm, so the disease spread through all the farms W, X, Y, and Z. In all there were about 160 cows. By examining two milkers I obtained the following history. They said that the teats swelled, were hot to the touch, and very tender. As a result the animals were milked with difficulty. The milkmen resorted to the standing position, as otherwise they and their milk-pails were upset. In some cases the pain on milking was so great that the animals became almost unmanageable and had to be tied by the legs. One man described the pain caused by milking the severe cases as "most barbarous." They stated that a little white bladder would rise up on the teat, which would become as large as a pea or much larger, and then was burst in the milking. As a result a sore formed and became covered with a scab. Matter formed under the scab, and as the scabs were broken in milking, matter and blood would come out on their fingers and get mixed with the milk. Sometimes the scabs would become rubbed off, in other cases they fell off, and finally in four or five weeks the sores would be healed.

The disease in man.—At these farms I found that the disease had been communicated to several of the milkers. They had been inoculated some weeks before my visit, so I had at this stage no opportunity of seeing the early changes. I had therefore to rely a great deal on their description. I will select a few cases.

Cowman R—— showed me a scar on his right hand. He said he was the first to catch the disease. It came as a hard painful spot, which formed matter and then a big scab. He had continued milking ever since, but had no fresh "placea."

Cowman F——, about a month ago, noticed spots which appeared on both hands. His fingers swelled and were painful. He says it came first like a pimple and felt hard. Then it "weeped out water" in four or five days. There were red marks creeping up his arm. There was a sort of throbbing pain, and he could not sleep at night. When I saw him I found on the right hand a scar, but on the left hand there was an ulcer about the size of a shilling covered with a thick black crust. The crust was partially detached and exposed a granulating ulcer. It was the exact counterpart of an ulcer on the cow's teat.

Cowboy H—— had both hands bad about a month ago, first the index finger of the left hand and then the right hand. He says that it came up like a hard pimple, and the

Digitized by Google

finger became swollen and red. After a few days it "weeped out" water and then matter came away. Both his arms were swollen, but his left arm was the worst. About a fortnight afterwards he noticed "kernels" in his armpits, which were painful and kept him awake at night. His arms became worse, he could not raise them, and he had to give up milking. He also had a bad place on the lower lip. On examination I found that the axillary glands were still enlarged and tender. He volunteered the statement that the places were just like the sore teats.

H——, the bailiff's son, had a sore on the upper lid of his right eye and left hand. In both places he had previously been scratched by a cat. The right hand had also been infected. It commenced, he says, a fortnight ago. His hands were swollen, red, and hot. He felt very poorly and went to bed. Little spots like white blisters appeared on the back of his right hand; these broke and "rose up" in thick scabs. He was very ill for two or three days, but did not send for a doctor. He had painful lumps at the bend of the arm and in the armpit. He gave up milking, and had not taken to it since.

Absence of scarlatina among consumers of the milk.—As I have said, there were altogether about 160 animals on these farms, and all, or nearly all, had contracted the disease. The milk was drunk on the farms and in the village, but most of it, amounting to eight churns a day—that is, sixty-four barn gallons, or 1088 pints,—was sent twice a day to a large city. Not being distributed in a wealthy neighbourhood, we may roughly estimate the number of persons drinking the milk at about 1500 or 2000. I was informed that there were no cases of scarlatina on the farms or in the village. In the town district in which the milk was distributed there was no epidemic. From these observations and researches, I think that we are justified in concluding that the disease I have described is identical with the Hendon cow disease. For—(*a*) In both cases we have an eruption confined almost entirely to the teats and presenting precisely the same appearance and with the same history. (*b*) In both, the disease is communicated from animal to animal by the virus being conveyed by the hand of the milker. (*c*) In both, the disease is communicable to man when the virus is received into abrasions or scratches on the skin, and produces, judging from the description, a similar disease. (*d*) In both, the disease is communicable by experimental inoculation. (*e*) In both there are occasionally the same constitutional symptoms, slight rise of temperature, eruption on the skin, patches devoid of hair, running from the eyes, &c. (*f*) In both there are streptococci associated with the disease, which are identical in every respect in their microscopical appearances and in their characters on cultivation. And therefore I am of opinion that we are justified in concluding that the Hendon cow disease was not scarlatina in the cow, and that in the Hendon cases the source of infection was from some unascertained human source.

Nature of the disease.—I now pass on to give you my opinion as to the nature of this disease. The appearance of the eruption, especially in the bailiff's son, aroused a suspicion in my mind, and on returning from my visit to the farm I very earnestly questioned some leading veterinary surgeons as to the nature of this disease in the cow. I was assured that it was very common and very well known, though not described in the text-books of veterinary medicine. It was referred by them to various causes. In deference to their opinion I even suggested that if it were an undescribed disease it might appropriately be termed a contagious mammillitis. But my suspicions clung to me, and were strengthened by studying the descriptions of affections of the teats in the cattle, and I expressed to several my disappointment at not having had an opportunity of seeing the earlier stages of the disease in man. I therefore determined to visit the affected farm again and again with a hope of seeing some fresh cases. On Dec. 2nd I was rewarded for my trouble, for in course of conversation with a head cowman my attention was drawn to a lad who was standing at some little distance. I was told that his was a new case, and an examination of his face revealed to me in a moment that my suspicions were well founded, for I was convinced *this disease of the teats of the cattle was the true Jennerian cow-pox.* My first impulse was to carry the boy straight off to London, but the question of accommodation led me to have advice first as to what course I should pursue. I therefore made a drawing of the boy's face, filled a number of tubes with lymph, and spent the rest of the day in visiting a farm I had not previously seen. Here I found a very intelligent head cowman whom I had not interviewed before, and I determined to elicit from him all he knew of this disease in his own words. He said that he had long known this disease of sore teats, and that twenty years ago he had had the sores on his fingers, just in the same way as the lads now on the farm. He added that he had no fear of milking the cows, because he was sure he would not get it again. I then asked him to tell me exactly what occurred in the teat from the very first, and he said that it began as a hard pimple on the red teat, that this got a white head, and then there came a blister with watery fluid, which was subsequently broken in the milking. Another cowman added that he had seen the watery fluid get like "brainy stuff" before the blister was broken. Thus, the history of what occurs must be as follows: First, there is a papule and then a vesicle, with first clear and then turbid contents. The vesicle on or before the turbid stage is ruptured by the hand of the milker, and the normal course of development of the pock is interrupted. The irritation of milking twice daily causes extensive ulceration and consequent formation of large fissured crusts; and thus, instead of getting well in about a fortnight, the disease is prolonged for four or five weeks or longer, and when finally healed there is an irregular scar. It is the hand of the milker which is responsible for the striking differences in appearance from the normal pock, such as the absence of pustule and pitting; but as for the reported absence of the initial papule in the Hendon cases, this is easily accounted for by Dr. Cameron's admission that for the earlier symptoms he relied on the statements of others. No doubt these accounts were incomplete, as in the first milkers' description to me. On returning to London in the evening, I confided my convictions to Dr. Curnow, and asked his advice as to bringing the boy to London. Dr. Curnow very kindly arranged to have him admitted to the Seamen's Hospital, Greenwich; and on the following day (Dec. 3rd) I persuaded the boy to accompany me there so as to have him under observation. I shall not trouble you, Sir, with full details of this case; but his condition at various stages is represented in these drawings. Suffice it to say that it was a most typical pock, and that lymph taken from the vesicle produced in the calves typical vaccinia.

Diagnosis from spurious forms of cow-pox.—The characteristic development of the pock on the boy's face and the production of typical vaccinia in the calf with the lymph were the conditions necessary for proving conclusively that this was the true cow-pox. The spurious forms are local eruptions on the teats, and are some of them communicable to the hands of the milker. They were recognised by Jenner,[2] Hering,[3] and Ceely,[4] and stress was laid on the necessity of being able to diagnose them, as they afforded no immunity from small-pox. There is only one form—the white or blister-pock—which is likely to cause difficulty in diagnosis. This disease is of short duration. The vesicles are only subepidermic, attain their height in twenty-four hours, are not truly umbilicated, and have no areola, and after bursting form a thin scab. There is no fever.

General remarks.—Now, Sir, the question may occur to you, Is this micrococcus identical with the virus of vaccinia? I am devoting my attention to this and to the study of any other organisms which may be present in the lymph. If it be true that the same streptococcus occurs in scarlet fever, diphtheria, puerperal fever, in improperly preserved milk, and perhaps, too, in foot-and-mouth disease, there can be but little doubt that we have only to deal with a micro-organism, which, when cultivated and inoculated in healthy animals, is capable of setting up a septic inflammation. Indeed, the post-mortem appearances observed by Dr. Klein point, in my mind, only to septic complication, which may equally occur in cow-pox, in scarlatina, and in other febrile diseases. I think that the explanation of this micrococcus being found occasionally in scarlatina is that, in severe cases with ulcerated throat, the blood is unable to cope with the invasion of micrococci from the surface lesion. If this be so, the opinion which I wrote early in 1886 concerning the micrococci which had been described in measles applies also to this micrococcus—viz., that in this and in many other cases I only described these organisms as distinct species "from their association with particular diseases, not because they are believed to be

[2] An Inquiry into the Causes and Effects of the Variolæ Vaccinæ, &c. 1798.

[4] Trans. Prov. Med. and Surg. Assoc., vol. viii., 1840, and vol. x., 1842.

Digitized by Google

causally related, for there is very little evidence in favour of that belief as yet, but purely for convenience of reference. In many cases they are probably only septic organisms which have found a pabulum in dead tissue; others appear to be identical with organisms which have been found in pus."[5]

Conclusions.—As the practical outcome of this research, I would strongly urge that prompt measures be enforced for isolating diseased animals, and preventing the spread of the disease through the herd. And as the milk is liable to be contaminated with blood, pus, and discharges from the teats, I consider that it would only be consistent with the most elementary rules of sanitation that only the milk obtained from the healthy cows in the herd should be sent into the market. Such measures, I trust, will lead to the alleviation of much suffering in the cows, ensure greater cleanliness in the milk, and provide another source of vaccine for public use.

THE CENTRAL NERVOUS SYSTEM AND AXIAL SKELETON IN ANENCEPHALOUS MONSTERS.

BY ALFRED W. HUGHES, M.B., M.R.C.S.,
FORMERLY SENIOR DEMONSTRATOR OF ANATOMY, ROYAL COLLEGE OF SURGEONS, EDINBURGH.

THE following description of parts in this comparatively rare form of monstrosity is taken from a seven months' anencephalous fœtus which I recently examined and dissected.

The well-known deficiency which exists on the dorsal surface of the fœtus extended from the head to the sacral region in the form of a broad shallow groove, on the floor of which the spinal cord lay exposed, which terminated above in a well-marked medulla oblongata. The groove of deficiency was broadest at its upper part, and narrowest at its middle, where the sides approached each other, more than at the two extremities. The sides of the groove were formed by the rudimentary laminæ of the vertebræ, which normally grow backwards to enclose the spinal cord, but which here are deficient. In the cervical and lumbar regions the laminæ were distinctly everted and almost in a line with the transverse processes, while in the dorsal region they were turned inwards and approached each other, giving rise to the narrow part of the groove above mentioned, and showing a tendency to the conversion of the groove into a canal as it normally exists. At the upper part, in the occipital region, the groove was bounded by an incomplete ring of bone, formed by a part of the occipital, which I shall again describe more fully, and to this ring of bone a strong fibrous membrane was attached which extended a short distance, partly covering the nervous structures contained in the occipital part of the groove, to which I shall again refer. Outside the ridge formed by the laminæ the skin terminated abruptly, the whole groove being devoid of skin; but covering the various structures lying in the groove was a thin, delicate, transparent membrane, which, traced outwards, was found to become continuous with the skin outside the laminæ, and, traced inwards, became attached to the spinal cord, but which had no attachment at all to the subjacent laminæ, and could with ease be lifted from their surface. This membrane, I have ventured to suppose, is of epiblastic origin, from the connexion which it has with skin and spinal cord, which structures are also developed from the epiblast, while the laminæ, to which it has no attachment, are developed from the mesoblast. The spinal cord extended downwards within an inch of the lower end of the groove of deficiency, and possessed its two well-developed symmetrical halves, separated by a well-marked dorsal fissure, which remained unclosed, and which terminated inferiorly in a rhomboidal space, corresponding probably to the rhomboidal dilatation, which remains for a time at the lower end of the central canal of the cord in a normally developed fœtus. The medulla was well developed, and on its dorsal surface the fissure continuous with that of the cord could be traced up to a well-marked fourth ventricle, overhanging which was a very small yet recognisable cerebellum, which was connected to the medulla by two distinct nervous bands, the inferior peduncles, which partly bounded the fourth ventricle. Lying just above the cerebellum was a large rounded mass (non-nervous), whose nature I at first could not make out, but upon incising it I found it contained a cavity filled with blood, and was therefore of the nature of a venous sinus; to this sinus I shall again refer, as it has certain important connexions. This mass was partly covered by and attached to the fibrous membrane before mentioned. The different nerves which arise from the medulla—the ninth, eighth, and seventh pairs—were well developed, and passed outwards to enter their respective foramina, the auditory also receiving fibres from the cerebellum. On tracing the medulla upwards, continuous with it was found a small mass of brain substance, from which several nerves passed out—viz., the optic, the third, and the fifth; but beyond this no trace of brain substance could be found. I dissected the optic nerve very carefully, and found, on the removal of the roof of the orbit, that the eyeball and parts in relation to it were well developed, with the optic nerve in its normal position, having its dural sheath, which was attached to the margin of the optic foramen. The nerve was traced back to the small mass of brain substance from which it emerged, but the optic commissure was absent, the nerve passing directly forwards to the eyeball of the same side, and having no connexion with the opposite nerve. I could find no trace of the olfactory tract or bulb. This mass of brain substance, from its position, and also from its close relation to the cerebellum, I at first thought was the pons Varolii, but the fact that from it the above nerves emerge suggests the idea that it must represent something more than the pons, for the optic nerve which passed out of it was well marked, and this in its development has no relation to the pons Varolii. It may be noticed that the only parts of the brain which were recognisable were those developed from the posterior primary vesicle—pons, medulla, and cerebellum; but the mass of structure, though extremely rudimentary, which occupied the position of the pons, must have a relation developmentally to the anterior and middle primary vesicles also, seeing that the optic nerve emerges from it, which nerve is developed from the mesencephalon and thalamencephalon, which belong to the middle and anterior vesicles respectively; but the remaining part of the anterior vesicle—viz., the prosencephalon, from which the cerebral hemispheres and the olfactory bulb are developed, seemed to be entirely absent. As to the bones of the head, I have previously mentioned the incomplete ring of bone formed by the occipital, to which a fibrous membrane was attached, and close to which I found a rounded mass of fibrous tissue having a large venous sinus in its interior. This sinus communicated with another sinus on each side, which passed outwards at the junction of the bone and fibrous membrane, and was traced to the jugular foramen. This sinus was therefore the lateral sinus, the central large sinus representing the torcular Herophili, and the parts of the occipital bone here represented are the ex-occipitals and the tabular portion of the bone which lies above the transverse sinus, while the tabular part which lies between the transverse sinus and the foramen magnum was absent, or was merely represented by a fibrous membrane, which had not become ossified. The frontal and parietal bones were well ossified, and formed a flattened compact case, which lay in close contact with the floor of the cranium, the clinoid processes of the sphenoid touching the under surface of the cranial roof; the interval between the floor and roof of the cranium was too small to admit even the handle of a scalpel. Unlike the normal fœtal head, there were no fontanelles, for in the position of the anterior fontanelle the bones forming the coronal, frontal, and sagittal sutures met in a point, the sutures forming a rectangular cross. The same condition existed at the junction of the lambdoid and sagittal sutures in the position of the posterior fontanelle. The floor of the cranium was normally developed. I have but merely alluded to the parts of the brain which are not represented in the fully grown anencephalous monster; but seeing how completely the optic nerve and eyeball are developed, while the rest of the structures developed from the middle and anterior cerebral vesicles are absent, one is naturally led to suppose that these vesicles at one time did undergo a certain amount of development, which afterwards became aborted, giving place to retrogressive changes,

[5] Manual of Bacteriology, p. 201.

Digitized by Google

though this opens up a field of investigation into which I must refrain from entering at present, not having the opportunity of examining the brain in this form of monsters from its earliest stages of development.

Flint.

A CASE OF HYSTERO-EPILEPSY SUCCESSFULLY TREATED BY REMOVAL OF DAMAGED UTERINE APPENDAGES.

BY LAWSON TAIT, F.R.C.S., &c.,
PROFESSOR OF GYNÆCOLOGY, QUEEN'S COLLEGE, BIRMINGHAM.

THE husband of this patient, a well-known physician in Rome, applied to me early in August concerning the sufferings of his wife, and he has given me the following history of the case. She was thirty-three years of age last July; she was married at eighteen; the first child was born ten months afterwards, the labour being natural and the convalescence perfect. In 1874 she aborted at the third month, the pregnancy being twins. The cause of the abortion was accredited to an accident, by which she fell downstairs. This abortion was followed by pelvic peritonitis on the right side, which seemed to centre in the Fallopian tube, and she was unable to leave her bed for three months. One year afterwards she aborted again, and on this occasion a similar inflammatory attack occurred on the left side; but she was not so severely ill as on the previous occasion. Her second convalescence, however, was very protracted; she never regained her ordinary strength; was unable to walk without suffering from pain in the pelvic fossa, which was greatly intensified at each menstrual period; and ever after the first abortion she was altered in temperament, and became *exalté* and irritable. For four years after the second abortion marital intercourse had to be avoided on account of the intense suffering it occasioned. In the spring of 1885 she was attacked for the first time with a convulsion, which lasted for about an hour, and similar attacks were repeated for two months, twice in twenty-four hours, which were very violent, sometimes requiring five or six persons to hold her. During the following two months they diminished somewhat in violence, in length, and in frequency, and quite disappeared in May, 1885. During that time she made frequent attempts at suicide, and her husband did not consider it safe to leave her without the constant presence of a nurse day and night, until December of the same year. During 1886 she had no attack, but was very feeble, very highly excited at times, and alternately in a condition of despondency. On Jan. 2nd, 1887, she was suddenly seized with violent trembling, which passed into convulsions, and these lasted for four hours. Similar attacks occurred daily, sometimes twice a day, until the middle of March. On May 15th she was removed from Rome to Lugano, it being her husband's intention, as soon as she was able to travel, to bring her to England for the purpose of having an operation performed for the removal of the uterine appendages. At Lugano she had a period, during which she was worse than ever; for most of the time she was in a condition of convulsion, and for the greater part she was unconscious.

Her husband communicated with me by letter on August 5th, to tell me of her condition. His letter is as follows: "The day before she was to start she was again seized worse than ever, the convulsions lasting from three to four hours, followed by wild delirium; for days she had no sleep. This continued for eight days, then she began to improve, and I was hopeful of getting her to England by easy stages. But ten days since she became worse, and the mania that followed was of a suicidal character. I am satisfied nothing will be of service except removal of the uterine appendages, as those on the right side have been diseased for the last eleven years. During the present attack there has been great tumefaction over the right ovary and tube, with fever and intense pain. Four days since a considerable quantity of fetid, greenish-yellow pus escaped from the uterus; in my opinion it came from the tube. Since then she has been better, and there has been less tumefaction. I cannot operate on my own wife, and I propose that you should do the operation. Please write and tell me when I had better bring her." I replied by telegram, that it seemed to me impossible to move the patient under such circumstances, and that I would run over to Lugano for the purpose of placing my services at his disposal. He replied by telegram to the effect that she was too ill to permit of such delay, and Professor Porro of Milan was called to see her. On Aug. 17th I received from the husband the following letter: "Professor Porro commenced his operation yesterday at 11 o'clock, and finished by abandoning it at a quarter-past 12. He made an incision three inches and a quarter long. He says both tubes and ovaries were so densely adherent that it was impossible to separate them from the mass of organised tissue in which they were embedded. The slighter adhesions he broke up, and then crushed the base of the ovaries with strong forceps, with the hope, he says, of partly destroying their function. He wished me to feel the attachments, but I declined, as I preferred to leave all responsibility with him. She suffers dreadfully. I give her as much morphia as I dare, but there seems no possibility of controlling it entirely. There is constant nausea and vomiting; the pulse is very weak and compressible (80); temperature 99°. If my poor wife recovers sufficiently, and you think there is a possibility of help in the future, I shall bring her to you." She recovered from the operation, and on Aug. 30th I received a letter from the husband to the effect that he was coming over to England to confer with me on the subject of future interference. But on his road he received in London a telegraphic despatch that all the symptoms, including the violent convulsions, had returned with, if possible, greater severity. To continue the history from that day in his own words: "I told Dr. Solaro of Lugano, in whose care I left her, that I expected a return of the convulsions, and in the event of that happening he was to notify to me immediately, when I would return with Mr. Lawson Tait, as the appendages must then be got out at any risk. On Sept. 18th I received a letter from my daughter stating, 'Your worst fears have been realised, the convulsions have returned as bad as ever, and she remains unconscious.' Next morning came a telegram which informed me that four violent convulsions had occurred in thirty hours, and this was followed by another that she was insane. I replied, 'Send to the asylum for help; I leave here to-night with Tait.' I saw him in Birmingham next morning, and he left with me by the next continental express, reaching Lugano on the 22nd. He operated on the 23rd with an incision not over two inches, and removed the appendages from both sides without any apparent difficulty. The operation from commencement to finish occupied exactly nine minutes and a quarter. The patient has had no trouble since; is bright and cheerful; has a better appetite than at any time during the last three years; the expression of the face has entirely changed; the old, haggard, anxious, irritable look has gone, and in the place is a contented, peaceful expression. I can only conclude by saying your skill has saved the reason and life of my wife."

At the operation I found the uterine appendages, as Professor Porro had, densely adherent, both tubes occluded, and contained certainly not more than a teaspoonful each of limpid serum. The patient has had up to the present time no return of her previous symptoms. I can, with such a narrative, only say that it is idle to talk of hydrosalpinx being a harmless condition which may be always left alone.

Birmingham.

FIFTY-FIVE CASES OF OPERATION FOR THE RADICAL CURE OF HERNIA.

BY ARTHUR NEVE, F.R.C.S.E., &c.

As this subject is now being discussed, I venture to summarise briefly the operations in the Kashmir Mission Hospital since 1881.

In that year Dr. Downes (now of Eastbourne) performed Spanton's operation in eight cases, of which one recurred at the time, and I have since seen another with recurrence. In the following year he performed three Spanton's, and three by ligature and excision of the sac (Annandale's operation). Of the latter, one died; of the former, one recurred. In the same year (1882), I performed two Spanton's operations. In 1883 I performed six Spanton's operations, of which one recurred, and two by ligature and excision;

Digitized by Google

of these latter, one died of shock. In 1884 there were three Spanton's operations, with one recurrence. The instrument used throughout this and following years was a straight shaft with a spiral point, by which the pillars are alternately pierced. I described the operation in the *Edinburgh Medical Journal*, and published full details of the cases in the *Indian Medical Gazette* for 1883, so will not recapitulate my experience. In 1885 I performed four Spanton's operations, with one recurrence after a year; and two other surgeons also operated on two cases, which rapidly recurred. Last year (1886) eleven Spanton's operations were performed, of which one recurred. This year, up to date, eight screw operations have been performed, of which two were followed by reappearance of the hernia. In one the recurrence was sudden and complete, with some pain. On the same day I performed herniotomy, excised the sac, and sutured the pillars. Another case of excision has since been also successfully performed. The total may thus be tabulated: Screw operations, with Mr. Dunnet Spanton's or the author's modified instrument, forty-eight cases (seven of these are known to have recurred); operations with ligature of the neck, and usually excision of the sac, seven (of these two died).

On these cases I will offer but very few remarks. With regard to the only really *radical* procedure, that of removal of the sac with suture of the canal, it is a somewhat severe measure. Without selection of cases, I doubt whether the mortality would be less than 5 per cent. By careful selection of cases it might not exceed 1 or 2 per cent. With only the latter mortality this operation for the radical cure of reducible hernia is justifiable; but the operator ought to avoid exposing old or weakly persons to an operation which is usually followed by more or less suppuration in the scrotum, and which is liable to graver complications. I consider Spanton's operation a less certain cure, but cannot speak positively on this point. During the last year I have usually removed the screw at the time, merely using it as an instrument for suturing the pillars and neck of the sac with silver wire, which has been left in. But this method seems to me less secure than that of leaving the instrument in for a week or until it loosens. This operation appears free from danger to life; in fact, the statistics collected by Mr. Spanton prove it to be so. Like Wood's operation, the success depends on the skilful application of the instrument. There is perhaps a "knack" in it, which many surgeons without considerable practice might fail to acquire. This should tell against the general adoption of the operation, but affords no ground for decrying its actual achievements. It is, moreover, a simple operation, and one in which the beginner is likely to fail from over-caution rather than otherwise, the operation being simply inert. In my first thirty cases it is likely that 20 per cent. recurred; in my next thirty this percentage is likely to be halved. Any who are interested in this subject should refer to Mr. Spanton's papers in the *Medical Times*, 1885, or to my contributions before referred to.

Kashmir, India.

HYDATID DISEASE OF THE CONVEX SURFACE OF THE LIVER,

DISCHARGING INTO THE PLEURA AND AFFECTING IT SECONDARILY.

BY H. HANDFORD, M.D., M.R.C.P.,
PHYSICIAN TO THE NOTTINGHAM GENERAL HOSPITAL.

THE history of the case is shortly as follows:—A man aged sixty-one, a lacemaker, was admitted under my care into the Nottingham General Hospital, in November, 1886, complaining of troublesome cough, slight muco-purulent sputum, and great shortness of breath, especially on exertion. He was well nourished, and had been a strong man, except for some winter cough for the last few years. His present illness had begun three months previously, and he had been sent into the hospital, with a diagnosis of chronic pleuritic effusion, for the purpose of being tapped. He had the signs of a moderate pleuritic effusion on the right side, but the vocal resonance and fremitus were very little diminished. The liver was not much pushed down, neither was it appreciably enlarged or irregular. He was aspirated, and thirty-four ounces of opaque semi-purulent fluid withdrawn. It was highly albuminous, but did not gelatinise on standing, showing the absence of any large amount of fibrine. Under the microscope very few pus cells were found and no hooklets or membranes, or anything suggestive of hydatid origin. The opacity appeared to be due not so much to pus as to the fatty degeneration of insoluble albumen—that is to say, of a highly fibrinous and albuminous exudation. The chest was aspirated twice again, at intervals of about three weeks, and after two months he was discharged practically well. He worked at his trade for six or eight months, and began to get short of breath again and to be troubled with cough in August, 1887. In the end of September I was asked to see him in consultation with my friend Dr. Stafford. The patient was extremely ill, with the right side almost motionless and dull up to the clavicle. He had the most urgent dyspnœa, febrile temperature, and coated tongue. Next day he became an in-patient again, and about fifty ounces of pus were removed by aspiration. This was examined microscopically, but presented no unusual appearance. There were no hooklets and no membranes. Rather more than a week later, when he had somewhat recovered strength, the chest, which had filled again, was opened by a free incision by my colleague, Mr. Wright. The opening was made in the seventh space, a little behind the posterior axillary line. The ribs were so close together that a small portion of bone had to be removed in order to admit a full-sized indiarubber drainage tube. After five or six days numerous hydatid vesicles appeared in the wound and on the dressings. Their true character was verified microscopically by the laminated hyaline appearance of the cyst walls, and by the presence of numerous hooklets. The cysts continued to be discharged almost daily for about a month; but for ten days or more before his death, which occurred from asthenia, the discharge of hydatids ceased. There never had been any noticeable enlargement of the liver. At the inspection a thick-walled, irregular, indurated, suppurating cavity, large enough to contain about six ounces, was found in the convex surface of the liver, chiefly in the right lobe, but partly in the left, immediately below the diaphragm. It communicated by a smooth, rounded opening, that would just admit the index-finger, with the right pleural cavity. In the pleura, at the root of the collapsed right lung, was a single hydatid cyst the size of a walnut. This was the only trace of hydatid left. There was no evidence of there having been any growth of hydatids in the lung, or any extensive affection of the pleura. The majority of the hydatids discharged through the chest wall—they numbered upwards of 100—must have come from the liver through the opening in the diaphragm mentioned above. The disease was cured, with the exception of the one solitary cyst at the root of the lung, but the patient had not strength to enable tissue repair to progress properly.

With regard to the diagnosis, I should say that the dependence of the chest affection on hydatid disease was not suspected till the vesicles were discharged, and then their origin from the liver was thought probable. The only difficulty during life in accepting a hepatic origin for the cysts was the total absence of bile staining. In a case of hydatid disease of the liver in a lad who was under my care in 1879, and which discharged through the lung, the numerous and large cyst walls which were coughed up were all stained of a bright orange-yellow colour. I have kept the patient under observation more or less ever since, and he is in robust health at the present time. With regard to the relation of the pleural effusion to the hydatid disease, I think it probable that the effusion in November, 1886, was due to contiguity, and that the free communication with the pleura was not established till later.

THE LATE DR. HARVEY.—At a special meeting of the County and City of Cork Medical and Surgical Association, held recently, the following resolution was passed unanimously:—"That we, the members of the County and City of Cork Medical and Surgical Association, having heard with extreme regret of the death of Dr. Joshua Harvey, the founder of the Medical Club, and for many years a very active and esteemed member of the medical profession in Cork, beg to convey our deep sympathy to his family on the death of one who stood so deservedly high in the estimation both of the public and his professional brethren."

COCAINE IN THE VOMITING OF PREGNANCY.

By FRANK COLLINS, M.R.C.S.

WITH reference to Dr. William Duncan's recent observations on this subject, I send the following case as an additional item of experience.

On Oct. 26th I was called in to consult on the advisability of inducing abortion in a case of continual and distressing vomiting, complicated with uterine hæmorrhage which the usual remedies failed to relieve. The patient was a primipara, aged twenty-seven, between three and four months pregnant. Vomiting began three weeks previously and occurred several times each day, gradually becoming more frequent until three days before I saw her, when it assumed so distressing a character after taking even liquid nourishment that she had kept nothing down for that period. The bleeding began with the straining fourteen days previously, and continued constant, but slight in quantity, though increased with each attempt at emesis. There was a history of delayed menstruation, but none of other disease. The patient was weak and exhausted, but not collapsed, complaining of "uneasiness," not pain, about the lower part of the abdomen. Pulse fairly good. Vaginal examination revealed a tender spot about an inch above the anterior lip of the cervix, and some tenderness of the cervix itself, from which drops of dark blood were exuding. Pelvic organs otherwise normal. With a tracheal sponge-holder I inserted, through a Ferguson's speculum, a plug of wool soaked in a 10 per cent. solution of cocaine to the depth of half an inch in the cervical canal, and retained it there from one to two minutes, afterwards swabbing the lips of the os all round with the same. The patient had vomited food taken some four hours before, and was expecting to reject some beef-tea taken a quarter of an hour before the operation. This did not occur, and all sense of "uneasiness" had disappeared before I left. Liquid food was taken and retained within an hour, and has been taken regularly ever since. The bleeding diminished by degrees, and the third day after the operation had entirely ceased, and the patient was doing well.

Seven days after the operation I learnt that the patient insisted on getting up and doing her household duties the day after the bleeding stopped. This was followed by a copious return of hæmorrhage, shortly succeeded by uterine pains; and the case will now probably terminate in miscarriage. The efficacy of the treatment appears to be emphasised by the patient's folly.

The points which appear to me worthy of notice are the almost instantaneous relief to the distress and nausea, and the absence of recurrence of those symptoms. Has cocaine some permanent action beyond its transient effect of causing local anæmia and anæsthesia?

Adelaide-road, N.W.

RECURRENCE OF SCARLET FEVER SYMPTOMS.

By STAFF-SURGEON FRENCH MULLEN, M.D.

(Communicated by the Director-General of the Medical Department of the Navy.)

HAVING seen in the THE LANCET of Nov 19th a letter from "M.R.C.S." giving an account of the recurrence of the symptoms of scarlet fever in a child a few days after her discharge from hospital cured of that disease, and the editorial comment that "such cases are undoubtedly rare," I think the following case may be of interest to the profession.

R. C——, aged thirty-five, stoker, presented himself on the evening of Nov. 8th, 1868, at Chatham, complaining of rigors, headache, thirst, and malaise, which symptoms, he stated, had commenced the previous day. The following morning sore-throat appeared, and a bright red rash was uniformly spread over his trunk and extremities. He was immediately sent to hospital, where the diagnosis of scarlet fever was confirmed, and he was retained until Dec. 15th, when he returned to his ship. In the following June (1869) he again suffered from similar symptoms at Portsmouth, and complete desquamation took place. In July (1869), at Portland, the same symptoms recurred, but were milder and of shorter duration. Owing to the improbability of a patient having scarlet fever three times in nine months, the two later attacks were looked upon as a species of erythema, and were treated on board, and though no special precautions were taken, no spread of infection took place.

In this connexion the following case may be worth recording.

G. R——, aged twenty, ordinary seaman, was placed on the sick list at St. Vincent, West Indies, on the evening of Jan. 30th, 1885, complaining of sore-throat, rigors, and malaise; the tonsils were ulcerated and the fauces deeply congested, being of an almost venous hue. Temperature 102°. The following evening a profuse red rash, which did not disappear even on firm pressure, appeared over the whole body, and the temperature rose to 103·6°. The disease ran the usual course; the throat was quite well, and the rash had almost completely faded, save on the inside of the thighs and legs, by Feb. 4th (sixth day), and branny desquamation set in. On this date an eruption of urticaria, but without itching, appeared over the trunk and extremities. It subsided in a couple of days. The patient was isolated on board, every possible precaution being taken. Desquamation was completed by Feb. 17th, on the 19th he suffered from a slight attack of sciatica, and on Feb. 27th he returned to duty. No extension of the disease took place among the crew.

Now this patient had not communicated with the shore from Dec. 9th, 1884, when the ship was at Halifax, Nova Scotia, to the date of his seizure, Jan. 30th, 1885; he had had no washing done on shore, none of his family at home were suffering from scarlet fever (which might have caused it to be conveyed by letter), and I could not find that scarlet fever was present at any of the West India islands visited, so that this was either a case of extraordinarily prolonged incubation (fifty-two days), or it was a species of erythema more severe than has been hitherto described. The eruption of urticaria on the subsidence of the erythematous rash lends support to this view. I may mention that I assured myself of the absence of gonorrhœa, and that the patient had not been taking copaiba, eating shell-fish, &c. The disease ran too regular a course for it to be symptomatic erythema; and so the fact of his having taken two fifteen-grain doses of the salicylate of soda prior to the appearance of the rash would not be sufficient to account for it.

THE MORE FREQUENT USE OF LONG FORCEPS IN LINGERING LABOUR.

By T. WOOD HILL, L.R.C.P., M.R.C.S., L.S.A.

IT is an unquestionable fact that the use of forceps is becoming more frequent, and is answerable for the great amount of relief to many a poor woman in the agonies of labour; so much so, that invariably when a poor creature has once had them used she naturally demands them again. In a highly nervous, excitable woman who dreads the pains of labour, what practice can be more judicious and productive of good than the administration of an anæsthetic and the application of the long forceps, and thus in the majority of cases terminate most cases of lingering labour? From my own practical experience I have seen far greater suffering relieved by such practice than by the old exploded doctrine of allowing nature to perform the task unaided. Certainly in some cases nature will, at a very great expense of acute suffering, terminate its work; not always satisfactorily—ruptured perineum or puerperal troubles may follow. But what is the good of having such scientific instruments at our own command, if we are not to use them in suitable cases? A woman, I maintain, ought not to be allowed to suffer unnecessary pain. Why should she? It has been my pleasure to help many a poor creature out of her trouble by the timely use of the long forceps; in primiparæ their proper use is even more satisfactory. When I look back at the cases of lingering labour that have fallen to my lot, a shudder comes over me to think I was not qualified to help nature. The more I see of difficult labour, the more certain am I that it is our bounden duty as medical men to minimise suffering; use the forceps and save suffering

SPINA BIFIDA, ACCOMPANIED WITH CONGENITAL MALFORMATION OF THE CERVICAL PORTION OF THE SPINAL CANAL.

BY JOHN H. LOVE, M.R.C.S.

I WAS called suddenly to a case of labour accompanied with flooding. I found the feet born, and the mother flooding. I delivered her of a female child, which was dead, and had its bowels protruding and the umbilical cord gangrenous. I immediately removed a very large placenta, when all hæmorrhage ceased. I found the spine of the child bifid from the second to the seventh cervical vertebra. The tumour (which had burst) surmounting the bifid portion contained a dirty chocolate-coloured fluid mixed with blood; the edges of the tumour were bluish, and had a congested appearance. The spinal cord and nerves were adherent to the walls of the tumour. The bodies and processes of the second, third, fourth, fifth, and sixth cervical vertebræ were deficient. The neck of the child was short, bringing the child's chin close to the sternum. The face and conformation of the head resembled that of a mask. It appears that about a fortnight previously the mother had sustained a great fright; for a son of hers (walking in his sleep) fell downstairs, and was found by her with his feet and legs stretched out, and his head, as it were, pushed down between his shoulders, presenting very much the appearance of this fœtal child when born.

Wolverhampton.

A Mirror OF HOSPITAL PRACTICE, BRITISH AND FOREIGN.

Nulla autem est alia pro certo noscendi via, nisi quamplurimas et morborum et dissectionum historias, tum aliorum tum proprias collectas habere, et inter se comparare.—MORGAGNI *De Sed. et Caus. Morb.*, lib. iv. Procemium.

ST. MARY'S HOSPITAL.

POSTERO-PARIETAL DEPRESSED FRACTURE; HIGH TEMPERATURE; TREPHINING.

(Under the care of Mr. PAGE.)

THE injury to the skull was in this case behind the motor region, and the only symptom, as far as could be told indicative of cerebral disturbance was elevation of temperature, which alone led to the use of the trephine, and which speedily subsided after the depressed bone had been raised. We are indebted to the dresser, Mr. C. Graves, for the notes.

T. P——, a butler, aged thirty-six, said to have been fond of port wine, and some time ago to have been "queer in the head," slipped on Dec. 31st down some doorsteps and struck the back of his head against the scraper. He was unconscious for a moment, and then got up and walked by himself to St. Mary's Hospital. A jagged and bruised semi-lunar wound, an inch long, was found in the right parieto-occipital region, at a point midway between the occipital protuberance and the parietal eminence, about half an inch above the lambdoid suture; and corresponding with the wound, in direction downwards and outwards, there was a small rent in the pericranium, with a line of fracture, and distinct, though very slight, depression of the bone. The wound was cleansed and dressed by the house-surgeon, Mr. Lloyd, who, from the trivial degree of visible depression and the absence of any cerebral symptoms, deemed it unnecessary to adopt further measures. This was about 6 P.M. At 11 the same evening the temperature was 101·2°, and on the following morning (Jan. 1st), when the man was first seen by Mr. Page, it had risen to 104°. Other than the fact that he was perhaps a little drowsy or apathetic in his manner, there was no suspicion of cerebral or meningeal injury. He had no pain, his pulse was 70, he expressed himself as being perfectly comfortable, and asked for more food. The high temperature, however, pointed to something amiss, and Mr. Page decided to trephine at once should no possible cause be found for it in the appearance of the wound. Exposure of the wound revealed a somewhat sloughy and shreddy, but yet quite sweet, condition of the deeper parts, possibly sufficient, it was thought, to account for the temperature. The wound was therefore again very thoroughly cleansed, brought once more into apposition, though without suture or strapping, and dressed with iodoform and wood-wool, it being the intention to trephine on the morrow should the temperature continue high. The temperature rose that afternoon to 105°, but before the evening it had begun to fall, and at 10 the next morning it was down to 99·4°. At the same hour on Jan. 3rd it was 99°, and the man himself felt perfectly well. He had no pain, but he still lay in the same dull, apathetic state, which further inquiry and knowledge of him proved to be merely his habitual manner. All looked well about the wound. On the afternoon of the 3rd the temperature again began to rise. At 6 P.M. it was 102°, at 10 P.M. 103·6°, and at 2 A.M. on the 4th it was 104°. The nurse thought he was "decidedly more drowsy," but he had no pain. There was no constitutional disturbance whatever, and all he complained of was insufficiency of food. There being clearly nothing now in the condition of the wound to account for the high temperature, Mr. Page decided to expose the bone more thoroughly and to raise any depressed portion which he might find. Accordingly, the head having been shaved and made perfectly clean by antiseptic washing, on the afternoon of the 4th he raised a large flap by semilunar incision, which included as its middle third the original laceration. The line of fracture was then found, as it had been feared it might be, considerably greater than it had formerly appeared, extending downwards and outwards in an irregular manner for three-quarters of an inch beyond the depression at first seen, and then returning on itself at a lower level in the form of an irregular V, lying on its side. At the apex of the V the depression was naturally greater than elsewhere; and it being found impossible to lever it up, an opening had to be made by the trephine, but the depressed bone was so tightly wedged down that even then it could not be raised, and a corner had to be sawn across and another portion removed. The resultant opening was of irregular shape—some three-quarters of an inch long by half an inch wide, the centre of it being midway between the occipital protuberance and the parietal eminence, four inches and three-quarters from the external meatus, an inch and a half from the middle line, and two inches and a half above a line drawn from the meatus to the occipital protuberance. The opening was therefore entirely in the parietal bone, and was situated about the posterior part of the temporo-sphenoidal lobe. The dura mater was found uninjured and healthy; and although the pulsation to be felt was but feeble and distant, probably from the position of the part exposed, it was thought wholly unnecessary to make an opening in it, there being no suspicion of subdural or subarachnoid pus. The parts were thoroughly cleansed with perchloride solution, the pericranium was restored to its natural position, a drainage tube inserted, and the scalp sutured into accurate apposition. The operation took nearly an hour, for three times had artificial respiration to be resorted to, because of failure in pulse and breathing. The temperature at 10 P.M. on the day of operation was 101·2°, and at 2 A.M. on the 5th had gone up to 104°; but thereafter it fell steadily to 100°, at which level it remained during the day. On the 6th it was down to normal, with one exception at 10 P.M., when it was 100·4°; but from this time onwards there was no further rise, nor did anything interfere with the immediate closure of the wound in those parts of it where recent and clean incision had been made. The lacerated part closed by secondary union, and his long stay in the hospital, until March 28th, was due to the continuance of slight discharge, which came from one corner, and which was kept up, not by any necrosis of bone, but by the irritation of a bad piece of catgut with which some vessel had been tied. His stay had this advantage, that it gave the opportunity of frequent examination, and of watching for the development of any symptome, sensory or motor, of brain lesion. Special regard was paid to his sight, but his optic discs, his fields of vision, and colour sense were throughout normal; his mental faculties were not impaired, no anæsthesia was ever detected, and the senses of taste and smell were perfect, although on March 6th it was thought that that of smell was not quite so good on the left side as upon the right. The difference, however, was not so marked as to lead to any suspicion of central mischief.

Remarks by Mr. PAGE.—This case is thought deserving of record, not for any light it throws on localisation of function in the convolutions of the brain, but as an instance

Digitized by Google

of disturbance in the cerebral equilibrium manifesting itself by elevation of temperature. The sequence of events shows that there was nothing in the wound to account for the rise, and it is most unlikely that any inflammation of brain substance, such as is found when there is surface suppuration, could have disappeared so rapidly after the pressure of bone was removed. The membranes were healthy, and so in all probability were the convolutions beneath. The depression of bone was insufficient to injure these subjacent structures; but, nevertheless, it was enough to affect the chief nerve mass in such a way as to upset the equilibrium which in health, and in a healthy state of these centres, subsists between heat adjustment, heat production, and heat loss. To follow the hypothesis of Dr. MacAlister in his Gulstonian Lectures, there was disturbance in the thermotaxic nervous mechanism, whereby a high temperature was developed, yet without fever. Speaking of this thermotaxic mechanism, he said that no one, as far as he was aware, had been able to say it was at this spot or at that. "Least and last developed, its organisation is necessarily the most imperfect," as it is necessarily the first and most easily disturbed of the three parts—thermolytic, thermogenic, and thermotaxic—into which he divides the thermal nervous system. The high temperature in the case here recorded may have been, it is thought, of this kind, and, if the interpretation be not erroneous, makes the case worthy of some attention. Suffice it here, in the inevitable uncertainty there must be upon this point, that a fracture of the skull in the posteroparietal region, with an amount of depression which by itself would hardly have called for operation, without visible injury to the parts beneath, was seemingly the cause of a high temperature, that that high temperature gave the sole indication for trephining, and was insomuch in all probability the means of saving the patient from more than one form of future danger.

When last seen (June 18th) the man was quite well, but more recent efforts to find him have been unsuccessful.

ST. BARTHOLOMEW'S HOSPITAL, CHATHAM.

FOUR CASES OF AMPUTATION THROUGH THE THIGH.

(Under the care of Mr. NANKIVELL.)

FOR the following notes we are indebted to Dr. R. T. Bowden, assistant resident surgeon.

CASE 1. *Compound fracture of both thighs in a man aged forty-seven, from railway accident, with compound depressed fracture of skull and other injuries; amputation through upper third of both thighs; secondary hæmorrhage and ligature of the femoral artery in the stump; recovery.*—J. M——, aged forty-seven, a navvy, was run over by a train on July 30th, 1887. He was admitted into the hospital an hour and a half after the accident, when he was found in the following condition. The right thigh had been completely severed from the body by an oblique wound passing through the lower half of the femur; the left leg was in a hopeless condition, the whole tibia being crushed, while there was an extensive lacerated wound laying open the knee joint, and the femur was fractured above the condyles; there was also a compound depressed fracture of the skull, involving the frontal and parietal bones on the right side, and the soft parts over the sacrum were extensively bruised. The general condition of the patient was bad, he was very much exhausted from pain and loss of blood, with small quick pulse, but was quite conscious.

Although the case seemed hopeless it was thought right to give him what little chance could be afforded by operation. Accordingly ether was administered, and Mr. Nankivell amputated both thighs through their upper third, by anterior and posterior skin flaps, with circular division of muscles; the stumps were dressed with eucalyptus and iodoform oil. During the operation, which lasted fifty minutes, the patient's condition improved considerably, the stimulating effect of the ether being very marked. No attempt was made to elevate the depressed fragments of the skull, as the depression was not great and there were no head symptoms; the wound was merely united by a few stitches and dressed with eucalyptus oil. In the evening he was very sick, and half a grain of morphia was given hypodermically. The following notes were subsequently taken:—

July 31st.—Slept fairly well last night. Feels comfortable. Stumps dressed. Temperature this evening 102·6°.

August 1st.—Doing well. Slept last night after a hypodermic injection of morphia. Stumps quite healthy. Temperature 100°.

2nd.—Stumps dressed; looking well. Complains of severe pain in the lower part of the back. Skin of right buttock red and very tender. Ordered a water pillow. Temperature this evening 99·8°.

5th.—A bed-sore has formed over the right buttock, where the skin was injured at the time of the accident. Dressed with zinc ointment.

12th.—Stumps doing well. The greater part of both wounds has healed by first intention. Stitches taken out. Bed-sore healing slowly.

22nd.—A large abscess which had formed over the sacrum was opened this morning. Stumps almost healed.

Sept. 5th.—This morning slight hæmorrhage commenced from the left stump; it proceeded from a cavity on the outer side of the stump, which had never healed. The bleeding was stopped without difficulty by a compress and bandage.

6th.—Hæmorrhage recommenced, and as it was much more severe than on the previous occasion, ether was given, and the stump being laid freely open, the femoral artery was exposed, with a small hole in it, about an inch above the lower end, from which the blood proceeded. A ligature placed just above this point did not arrest the hæmorrhage, as a large branch was given off a little lower down, and the collateral circulation had been fully established, so the vessel was tied above and below the opening, and divided between the ligatures. The wound was united by stitches, and dressed with eucalyptus and iodoform oil.

From this time the patient progressed satisfactorily. A large bed-sore formed over the sacrum where the skin had been injured at the time of the accident, and gave some trouble, but by the use of water pillows and careful dressing it healed slowly. He is now (Dec. 1st) practically well, and will be leaving the hospital very shortly; had it not been for a small abscess which formed in the left stump, he would have gone out some weeks ago.

CASE 2. *Compound fracture of the left femur and punctured wound of the right thigh; amputation through the upper third of the left thigh; secondary hæmorrhage from the right thigh, and ligature of the femoral artery; recovery.* C. B——, aged sixteen, was run over by a trolly on July 28th, and was admitted into the hospital an hour afterwards. On the left side there was a compound fracture of the femur into the knee joint and lacerated wounds of the thigh; there was also a second fracture of the femur a little above the middle. On the right side there was a punctured wound extending completely through the fleshy part of the thigh, and passing near the femoral artery; the skin of the calf was almost completely torn off, exposing nearly the whole of the gastrocnemius muscle, and the first metatarsal bone was dislocated from the internal cuneiform.

Ether was given, and the left thigh amputated through its upper third. The stump was thoroughly washed out with carbolic lotion (1 in 20) and dressed with antiseptic gauze. The wounds of the right thigh and leg were carefully united by stitches and dressed in a similar manner, and the dislocation of the metatarsal bone was reduced without difficulty. In the evening thirty-five minims of liquor morphiæ were given, and the patient had a good night.

A few days afterwards the skin of the right calf began to slough and a large healthy ulcer was left. With this exception all went well until August 9th (twelfth day), when, without any warning, violent hæmorrhage suddenly commenced from the wound in the right thigh. A tourniquet was at once applied by the nurse, which stopped the bleeding; but as soon as this was slackened blood again came out in jets. Ether was therefore given, and the wound laid freely open, when the femoral artery was exposed; in one part of its course a small hole could be seen, from which blood spurted whenever the pressure of the tourniquet was removed. The vessel was tied with catgut above and below the wound, and divided between the ligatures; the external wound was sewn up, and a drainage-tube inserted. The patient after this recovered steadily, the large ulcer on the right calf healed slowly under the influence of Martin's bandage and frequent applications of solid nitrate of silver, and on Nov. 2nd he was discharged from the hospital.

CASE 3. *Gunshot wound of the head of the tibia opening the knee joint; amputation through the knee joint; recovery.*—E. A——, aged thirty, a labourer, was accidentally

Digitized by Google

shot in the leg on Sept. 7th, and was admitted into the hospital five hours afterwards. The external wound was on the outer side of the right leg, about three inches below the knee joint. A thorough examination under ether showed that the upper end of the fibula was blown away, while nearly the whole charge of shot had lodged in the head of the tibia; numerous small holes, caused by isolated shot, surrounded the main wound. It seemed probable that the joint was opened, for a distinct grating sensation could be felt on moving it, and a bystander stated that some watery fluid (synovia) ran out immediately after the accident. A large number of shot were extracted and an artery, probably the peroneal, that had been wounded, was tied. The wound was stuffed with lint soaked in eucalyptus and iodoform oil, and a back splint put on.

For a few days the man progressed favourably, but then suppuration occurred in the joint, and amputation was rendered inevitable. Accordingly, on Sept. 12th Mr. Nankivell amputated through the knee-joint, making a long posterior flap, and removing the patella. Two drainage tubes were inserted and antiseptic dressings put on.

The subsequent history of the case presents no point of special interest; the wound healed rapidly, though recovery was somewhat delayed by an abscess which formed in the stump; but on Nov. 8th the patient was able to leave the hospital.

CASE 4. *Compound fracture of the femur into the knee joint complicated by delirium tremens; amputation of thigh; death.*—H. B——, aged fifty-six, a railway porter, was admitted on Aug. 30th, having slipped on the pavement and fallen half an hour before. There was a very oblique fracture near the lower end of the right femur, and the sharp edge of the upper fragment had made a small wound through the skin. The fracture seemed to extend right into the knee joint, which was somewhat distended with fluid.

Ether was given, and by means of extension and manipulation the fragments were got into fairly good position, and a long splint was put on, with extension, and the wound dressed with compound tincture of benzoin.

The next day the man pulled the splint off, and it was reapplied. A few days later he became wildly delirious, tore the bandages off, and made frequent attempts to get out of bed. A liberal diet without any stimulants was ordered, while chloral and opium were given freely; but for nearly a week the greatest difficulty was experienced in preventing him getting out of bed, and it was absolutely impossible to keep the fragments at rest. The joint had become acutely inflamed, but the condition of the patient forbad amputation. On Sept. 12th, however, there was a slight improvement in his general condition, and the thigh was amputated through its lower third. He bore the operation well, and for some days seemed to improve a little, lying quietly in bed and talking rationally; then the delirium returned; chloral was given, but with very little effect; paraldehyde was also tried, but seemed almost useless. He then gradually sank, and on Sept. 22nd he died.

Remarks.—The above cases all occurred within a space of six weeks, and they illustrate several points in connexion with the surgery of the lower extremity. Case 1 is very interesting. It is usually considered that amputation through the upper part of the thigh for railway accident is almost surely fatal; but here we have a recovery after amputation through the upper third of both thighs, and the case is the more remarkable on account of the age of the patient and the severe injuries he received to the head and back. It would be interesting to know if any similar cases are on record. The secondary hæmorrhage was apparently due to the ligature having been placed just below the point where a large branch was given off, so that not sufficient space was left for the formation of a clot. In Case 2 the injuries were of a somewhat similar nature, though less severe, and the age of the patient was much more favourable for recovery. It is certainly unusual to have an amputation of the thigh on one side and ligature of the femoral artery on the other. In Case 3 it was not quite certain whether the joint was involved or not, but in any case primary amputation was contra-indicated at the time of admission owing to the exhausted condition of the patient. It was five hours after the accident before he reached the hospital, and during that time he had lost a large quantity of blood. Any immediate operation would probably have been fatal, while secondary amputation proved most successful. Case 4 shows the difficulty of treating a bad fracture when complicated by delirium tremens; at first the skin wound was very small indeed, but the struggles of the patient soon made the whole end of the upper fragment protrude, rendering amputation inevitable.

Causes of Hypertrophy of Skull in Rickets, Mollities Ossium, Syphilis, and Osteitis Deformans.—Neurotomy of Third Division of the Fifth Nerve at the Foramen Ovale.

AN ordinary meeting of this Society was held on Tuesday last, Mr. G. D. Pollock, F.R.C.S., President, in the chair. A few words expressive of sorrow and regret on the decease of Sir George Burrows were given from the chair.

Mr. W. ARBUTHNOT LANE read a paper on the Factors that determine the Hypertrophy of the Skull in Mollities Ossium, Osteitis Deformans, Rickets, and Hereditary Syphilis. The author called attention to the desirability of separating the direct from the indirect effects of morbid conditions or diseases, especially in the case of those above enumerated. He referred to papers in the *Journal of Anatomy and Physiology* and in the Guy's Hospital Reports for 1887, in which he had explained the mechanical factors that determine the character of the deformities of the bones of the lower extremities in mollities ossium, rickets, and osteitis deformans. He had shown that these deformities are preceded and produced by a yielding of the sacrum in such a way that the lumbo-sacral articulation is displaced forwards and downwards from its normal relationship to the iliac bones and hip joints. This alteration in the position of a joint through which the whole superjacent weight of the head, trunk, and upper extremities is transmitted from that normally occupied by it, necessitates, when the erect posture is assumed, that the hip and knee joints be flexed, and a consequent tendency for the long bones of the leg to yield in a vertical antero-posterior plane. He had also demonstrated the factors that determine the yielding of these long bones in a vertical transverse plane. He obtained his first clue to the conclusions at which he had arrived from a study of the changes that the skeleton undergoes in old age, and of the laws governing them. He attempted to prove that the factors that determine the thickening of the skull in mollities ossium, congenital syphilis, rickets, and osteitis deformans are purely mechanical, and that the hypertrophy is not the direct product of the morbid condition or disease, but a vigorous attempt, and sometimes the only attempt, on the part of the organism to retain its most important organ as free from the direct result of the disease as possible. He referred to a paper in the Transactions of the Pathological Society, 1884, in which he had disputed Rindfleisch's theory of the processes which ensue in the skull in mollities ossium, and detailed the arguments by which he arrived at his conclusions—namely, that in mollities ossium the thickening of the skull is dependent upon an endosteal, and later upon a periosteal, deposit of decalcified lamellæ of fibrous tissue, this being not a direct product of the condition, but an effort on the part of the organism to oppose and limit the baneful influence of the process of decalcification in so far as it affects the cranial vault. He applied the same arguments to the analogous condition of the skull present in osteitis deformans, rickets, and congenital syphilis, with the object of showing that in them also the thickening of the skull was (in a similar manner) a process of repair and not a direct result of the disease.—The PRESIDENT referred to cases of curving of bones, and said that the new formation of bone took place on the concave side and thus strengthened the shaft; perhaps the new growth of bone in the convexity of the skull was of a somewhat similar nature.—Dr. ANGEL MONEY said that the explanation offered by Mr. Lane was ingenious but teleological, for we do not know that nature is so kind as to provide for all accidents.—Mr. HOWARD MARSH considered the paper suggestive. He referred to the strengthening of curved bones by the formation of buttresses of new bone in the concavity of the curve as perhaps due to an actual irritation. It was curious to observe how rickety bones became excesively thickened and how curved bones ulti-

Digitized by Google

mately become straight.—Mr. LANE, in reply, thought that a mechanical explanation was not a teleological one.

Mr. BLAND SUTTON contributed a case of Neurotomy of the Third Division of the Fifth Nerve at the Foramen Ovale. This paper contained the details of a case in which a man, aged sixty-four, suffered from frequent and severe attacks of epileptiform neuralgia, due to implication of the branches of the inferior maxillary division of the fifth nerve in a mass of epithelial cancer of the cheek. An operation was performed, and the third division of the fifth nerve divided as it issues from the skull. The difficulties encountered in this procedure were detailed, which ended in the subsequent ligature of the common carotid artery. Notwithstanding this, and in spite of the man's age, he recovered from the operation, was deprived of the neuralgic seizures, and lived in comparative comfort until he succumbed to his cancerous malady eight months later.—Mr. WALSHAM thought that the operation should not be lightly undertaken. He had stretched many of the branches of the inferior maxillary division of the fifth nerve. The inferior dental, the gustatory, the buccal, and the auriculo-temporal were the branches he had stretched, the first one six times. Stretching and not division should be employed; even in excision the nerve ends might grow together again. Stretching, though efficacious for some time, might in some cases not be permanent. He had removed Meckel's ganglion on one occasion, but this proved ineffectual.—Mr. HOWARD MARSH asked what artery was supposed to have been the source of the bleeding for which the common carotid artery was tied. In many cases ligature of the external carotid would be sufficient.—Dr. T. N. PEARSE asked what influence was exercised ultimately on the malignant growth by the division of nerves.—Mr. BLAND SUTTON said occasion for such an operation would rarely arise. The cancer had already implicated the muscles of mastication, so there was no need to pay attention to the motor nerves. The lingual nerves were often divided for carcinoma of the tongue. The internal maxillary artery was divided. Malignant growths possessed no nerves, and were not under the domination of nerves. Perhaps the ligature of the artery diminished the growth of the cancer.

CLINICAL SOCIETY OF LONDON.

Acute Enlargement of the Thyroid Gland in a Child.—The Surgery of Hydatid Disease of the Liver.

THE last ordinary meeting of the year of this Society was held on the 9th inst., Dr. W. H. Broadbent, F.R.C.P., President, in the chair.

Dr. THOMAS BARLOW read a case of Acute Enlargement of the Thyroid in a Child. The case was that of a boy aged three, previously healthy, and just recovering from a slight attack of erythema nodosum. The day after he had been taken out of doors he had a little nasal catarrh, and complained of pain in the neck. A slight enlargement of the thyroid gland was found. The whole gland was involved, but the left lobe more than the other parts. The enlargement increased, and gave rise to much pain and considerable dysphagia, and was attended with pyrexia as high as 103°. The acute phase lasted four days, and the total duration of the enlargement was about a fortnight. Great relief was obtained by the application of a single leech over the centre of the swelling. After the subsidence of the fever there was very great anæmia and some tendency to collapse, but the boy made a complete recovery to health after three weeks stay at the seaside. A summary of the literature of the subject was given in regard to acute enlargement of the gland as distinguished from goitre strictly so called. Besides the idiopathic, traumatic, and metastatic forms described by Lucke, reference was made to the epidemic variety recorded in connexion with French garrisons, and to thyroiditis occurring as a complication or sequel of acute and subacute rheumatism, and also of ague. The present case, from the fact that it succeeded upon erythema nodosum, might be considered to belong to the rheumatic variety, but no other rheumatic phenomenon was observed, and its severity was greater than that of the recorded rheumatic cases, the duration of which in their acute phase was not longer than forty-eight hours. On the whole, it seemed best to place the present case provisionally in Lucke's idiopathic group, and to accentuate its association with slight nasal catarrh and sequence on exposure to cold when in an anæmic condition.—Dr. STEPHEN MACKENZIE knew of a case. The patient was a young man of weakly health, but not really ill, since he attended a racecourse on the day of his sudden death, which resulted from an acute enlargement of the thyroid pressing on the trachea; a recent hæmorrhage into the thyroid gland and large white kidneys were found at the necropsy.—Mr. BERRY had seen a great number of such cases, and chiefly on the Continent—in Auvergne and in Switzerland. He had seen one in South Wales in a boy aged fourteen; the enlargement was rapidly fatal. A second case occurred in Wiltshire, in the person of a young girl who died from dyspnœa rather suddenly after a few weeks. In a similar case at Reading, also in a boy aged fourteen, he had secured the thyroid gland for the Royal College of Surgeons' museum. The occurrence of these fatal cases at puberty was a noteworthy point. Of twenty-seven cases in which the acute enlargement caused death, and in which no opening except tracheotomy was attempted, twelve occurred between the ages of thirteen and sixteen. Enlargement of the thyroid, not fatal, could, of course, occur at any age, sometimes very early, and even congenitally. The earliest age at which he had seen it was two years and a half. The relationship of acute thyroid enlargement to rheumatism was interesting; he had observed a case in the course of chorea; treatment with arsenic was followed by a cure. Although females were most frequently affected with goitre, still these fatal cases were as common in males as females. Of thirty-two cases, seventeen occurred in girls and fifteen in men. He asked why Dr. Barlow had come to the conclusion that in his case the enlargement was evidently not of the same nature as ordinary goitre; the microscopical changes were similar in all cases examined.—Dr. ANGEL MONRY considered that rheumatism was a cause of acute thyroid enlargement running a similar clinical course to the other manifestations of rheumatism. He related a case of a young lady in whom arthritis, erythema, and heart disease had occurred. He contended that in the rapid onset and rapid subsidence, with absence of chronic enlargement, we had characteristics which distinguished these idiopathic and rheumatic cases from ordinary goitre.—Dr. BARLOW, in reply, was interested in Mr. Berry's information, but drew attention to the distinction between cases such as he had described, in which pyrexia occurred and the thyroid swelling ran through a definite cycle and subsided completely, and ordinary cases of goitre in which more or less chronicity obtained.

Dr. COUPLAND read notes of a case of Hydatid Cyst of the Left Lobe of the Liver, which was radically cured by operation. The patient, a tall and pallid youth, aged seventeen, was admitted into the Middlesex Hospital on Jan. 22nd, 1887. For two years he had been getting weak and suffering from constipation, and for three months had noticed in addition a small and rather tender swelling in the upper part of the abdomen. Beyond his lassitude and somewhat hypochondriacal tendency, there was nothing special in his general condition. In the epigastrium there presented a hard nodule, the size of a nut, slightly tender, apparently connected with the left lobe of the liver, with which it moved freely on inspiration. The cardiac pulsation was also transmitted to it, especially during expiration. The liver was not enlarged; there was no jaundice. The patient remained under observation for nearly two months, without any failing of his general health, or any apparent change in the size or character of the small swelling. The diagnosis seemed to rest between a stationary innocuous growth or a shrivelled obsolete hydatid cyst, and exploration was decided on, with the view as much of relieving the patient's anxiety as of clearing up the diagnosis. Mr. Gould performed the operation on March 24th, and a hydatid cyst of the size of an orange was found embedded in the left lobe of the liver, projecting mainly on the posterior surface, but also to a slight extent on the anterior, where it formed the nodule previously observed. The cyst was punctured, and clear hydatid fluid containing numerous scolices evacuated. The cyst wall was then firmly stitched to the peritoneum, the abdominal parietes freely incised, and a drainage tube inserted. The case did well, and on April 3rd the collapsed hydatid was extruded; it contained two or three small daughter cysts free within it, besides having its endocyst thickly studded with scolices. Two days later the tough and fibrous adventitious cyst wall was also extruded. The cavity rapidly granulated, and the patient left the hospital on the 28th for a convalescent home. When seen a month later he was in excellent health. Thus the

Digitized by Google

exploration in this case resulted in the radical cure of the disease, the cystic nature of which it was not possible to determine by ordinary methods. The very solid nature of the presenting nodule prevented any recourse to the aspirator prior to the operation, whilst the lad has been saved the risks of rupture and suppuration by resorting to the exploratory incision in preference to leaving the case alone as one of "abdominal tumour of uncertain nature." Hydatid cysts are far less common in the left than in the right lobe of the liver, and it is rare for one to be treated by free incision in so early a stage. Although doubtless simple puncture might have sufficed to have lulled the parasite, there can be no question of the advantage of total eradication, if, as such a case seems to show, it can be made with almost equal impunity.

Mr. EDMUND OWEN read a case of Hydatid Tumour on the Upper Surface of the Liver successfully Tapped and Drained across the Pleural Space. A married woman, aged thirty-four, who was born and had lived all her life in London, came under Dr. Broadbent's care in May, 1886, on account of pains in the region of the right hypochondrium, and constant sickness. There was great fulness in the region of the liver, with dulness on percussion, which reached from the fourth rib nearly to the umbilicus. The right lung was greatly elevated and compressed. The hepatic tumour was smooth and hard, and gave no wave on impulse; it did not move with respiration, nor with any change of the patient's position. Aspiration removed thirty ounces of clear fluid, which contained no hooklets. In June another tapping was made, but with no result. In July, as the tumour was increasing, it was again tapped in the seventh space, sixty-eight ounces of bile-stained fluid coming away. This contained an abundance of hooklets. In the beginning of 1887 the patient was again admitted into the hospital. The tumour had increased, and there was danger of the cyst bursting into the thorax. Several aspirations were performed, with fairly satisfactory results. It was decided that the hydatid cyst, which was completely hidden behind the lower ribs on the right side, and was probably occupying the upper surface of the right lobe of the liver, must be incised and drained. On Feb. 14th this was done by making an incision in the eighth intercostal space, opening the pleural cavity. Air rushed freely in; the finger, introduced, readily felt the diaphragm, which was bulging up along the inner surface of the chest wall, but the lung itself, completely collapsed, could not be reached. The phrenic pleura was then incised, and with it the diaphragm. The finger, passed through the diaphragm, came at once upon the tense cyst, from which a considerable amount of fluid was withdrawn by aspiration, so that some of its surface might be dragged through the opening in the diaphragm and up to the skin wound. There it was fixed by four hare-lip pins, so that the wounded phrenic pleura might become glued to the wounded costal pleura; and that the cyst might be subsequently incised and drained without risk of leakage into the pleural space. The wound was dressed with wood-wool pads. On the fourth day (the patient's temperature never having reached 100°) the dressings were removed, and the cyst was incised. Bile-stained fluid escaped, and with it pieces of cyst wall, like rotten wash-leather. A large flanged drainage tube was inserted, and daily the cyst was washed out with warm iodine water, large pieces of cyst wall escaping. The woman made a complete and uninterrupted recovery. The pneumothorax gradually disappeared, as did also a slight effusion of fluid into the chest, and when Dr. Broadbent saw the patient a short time since she was well and fairly strong, whilst the lung had descended to its proper level. He alluded to a case in which Mr. Godlee a few months later had traversed a healthy pleural space to evacuate a lung abscess. In the latter case sutures had been employed to stitch the margins of the wound in the phrenic pleura to those of the wound in the costal pleura, but Mr. Owen was of opinion that hare-lip pins were more handy than sutures, and quite as effective for the purpose, and he would prefer them to sutures if ever he had to fix the lung to the chest wall, before proceeding to deal with a suppurating pulmonary cavity. It would be an interesting question as to how long it would take for the wounded and approximated pleural surfaces to become securely fixed by adhesive inflammation; perhaps it would be an affair of hours rather than of days. The tolerance with which the pleura submitted to the intrusion, the rapidity with which absorption of air and inflammation effusion from the space occurred, and the perfect manner in which the lung resumed its function after long-continued compression and after operation, were important and cheering features in the case, and offered further proof, were that needed, that the healthy pleura was as amenable to surgical trespass as was the synovial membrane of the knee joint or the peritoneum itself.

Mr. TREVES read a case of Extra-peritoneal Rupture of a Hydatid Cyst of the Liver. The patient, a married woman aged twenty-one, was "hugged" by her husband, who seized her round the waist and lifted her three times from the ground. She was immediately seized with intense abdominal pain, became very faint, and was sick. For thirty-six hours she was unable to lie down, and would not allow her clothes to be removed. Twenty-four hours after the injury a swelling made its appearance under the ribs of the right side. This swelling in time extended to the left of the median line. It was dull on percussion, but did not fluctuate. It was not affected by posture, was evidently below the subcutaneous tissues, and was not intra-muscular. The case was diagnosed to be one of subperitoneal hæmorrhage. No bruising was apparent, and no ribs were fractured. The patient had enjoyed good health, had never had a day's illness, had not suffered from jaundice, and had had no abdominal swelling. The tightness of her stays served to prove the last point. The swelling diminished at the end of a month. It now was more defined, was under the right ribs, and about the size of a child's head. It fluctuated, and could not be separated from the liver. The application of pressure, in the form of Martin's elastic bandage, caused a rise of temperature on each occasion of its employment. At the end of the second month the patient had become emaciated, and the swelling was very prominent. The tumour was incised close to the margin of the ribs. Hydatid fluid escaped, suppuration supervened, and the patient died, greatly emaciated, three months from the time of the injury. The necropsy showed that a hydatid cyst had formed in the posterior part of the right lobe of the linea close to the diaphragm. This had been ruptured by violence. The fluid had found its way into the subperitoneal tissues of the anterior abdominal wall. On the development of a second cyst—the one incised—the extravasated fluid had receded. The hepatic tissue of the right lobe was almost wholly destroyed. The case affords an example of extra-peritoneal rupture of a hydatid cyst of the liver.

Dr. ANGEL MONEY related a case of empyema due to hydatids that had been under his care at the Chest Hospital, Victoria-park. The patient spat up a translucent, jelly-like substance and laminated membrane with a great quantity of pus. Mr. Macready was called in, and excised a portion of the ninth rib; a large cavity was found in which abundance of hydatids existed, and were discharged at the operation to the amount of two large basinfuls. The hole in the diaphragm leading into the hydatid cyst in the right lobe of the liver was easily felt. A perfect recovery ensued. — Mr. GODLEE drew attention to the difference in the doctrine of treatment in this country and in Australia. In the latter country surgeons found aspiration to be sufficient, whereas in England subsequent operation was often necessary. He described various methods of procedure which could be employed, and expressed an opinion in favour of drawing the sac out, aspirating, and then extirpating it.—Mr. HARRISON CRIPPS had treated three cases. The first one by simple aspiration, which had to be repeated in a few months when pus was found, but the patient did well. Trocar and drainage were employed for the second case, and with success. The third case was explored as an obscure abdominal tumour; the hydatid was found, and its sac opened, a pint of pus escaping, after which the sac was removed entirely. Another cyst was discovered opening into the first; this was also opened up and removed, with a good result. In suppurating cysts it was best to open and remove the cyst wall.—Dr. DUFFIN had had two cases of hydatid in the left lobe of the liver. He did not believe in removing much fluid by the aspirator, but only enough to lessen the tension of the sac. In the first case, which happened in a girl, aspiration alone was successful. In the second, in a woman, the cyst suppurated and a free incision had to be made, when the numerous daughter cysts gave rise to some difficulty, but ultimately the case did well. In ordinary cases he would draw off only half an ounce if the cyst contained about thirty ounces. A secondary enlargement often followed, and then the fluid became albuminous. Really nothing

Digitized by Google

should be done for this secondary swelling, at least for some time, because gradual absorption was the usual consequence. If the swelling persisted for a long time, then further interference would become necessary. The second puncture was more dangerous and apt to set up the very thing which it was our object to avoid.—Mr. BARKER pointed out that in Russia, where cases of hydatid cysts were comparatively common, opinion was greatly in favour of performing the operation in two stages. He mentioned one surgeon who had not had a death in operations so carried out, whereas he had lost two patients by emptying the sac at once. He suggested that corroborative evidence on this point would be very useful.—Mr. HOWARD MARSH related the case of a boy where he had cut down on the cyst and sutured it to the margin of the abdominal wound. Some weeks later he opened the cyst, and the lad had done remarkably well. In another case at St. Bartholomew's Hospital he had sutured the sac to the wound and left it for five or six days, and he felt very strongly that that was the better course to pursue. He said that it really did not amount to making two operations of it, for opening the sac was a painless proceeding. He added that the general opinion of English surgeons was in favour of the two-stage operation. He had aspirated in children several times, and in one or two cases no recurrence had taken place, but recurrence did sometimes take place.—Dr. BROADBENT said that in a considerable proportion of the cases he had seen, simple aspiration had been sufficient to effect a cure. He could recollect at least half-a-dozen cases in which he had subsequently seen the patients. He mentioned that cysts varied in character, and said that he had remarked that when there were quantities of daughter cysts suppuration was very likely to take place; whenever the fluid came away easily, retrogression might be expected. In one case the struggles of the child caused laceration of the walls of the cyst and escape of the fluid into the abdomen. This, however, was absorbed, and the child got well. He was unable to reconcile this case with that related by Mr. Treves.—Dr. COUPLAND, in reply, said that most of the cases he had seen in which aspiration was employed, either suppurated or refilled. He suggested that one advantage of a free incision was that the presence of other cysts might be detected.—Mr. EDMUND OWEN, in reply, said he was disappointed that the discussion had not turned more on the extension of the cysts into the thoracic cage. As to the best operation to be performed, he said that in abscess of the liver it might be advisable to open the sac directly, but, on the whole, he preferred the method of doing the operation in two steps. He thought that there was no necessity for waiting so long or even for a few days, seeing that a few hours probably sufficed to obviate any danger of the fluid escaping into the abdomen.—Mr. TREVES, in reply to the President, said that the post-mortem examination of his case left no room for doubt as to its nature. He added that absorption did take place to some considerable extent.

The following living specimens were shown:—

Dr. HADDEN: Dry Tongue.

Dr. HERRINGHAM: (1) Atrophy of Thigh Muscles from Rheumatic Neuritis; (2) Chronic Atrophy of Leg in a Boy.

Mr. ALLINGHAM: Excision of Knee-joint.

MEDICAL SOCIETY OF LONDON.

Osteitis Deformans.—Acute Pneumoparesis.

AN ordinary meeting of this Society was held on Monday last, Dr. Hughlings Jackson, F.R.S., President, in the chair.

Dr. ELLIOTT of Hull contributed a paper on a rare case of Osteitis Deformans occurring in a young man aged twenty-seven, in whom the disease lasted about twenty-one months, and was probably complicated by multiple sarcomata in the skin and deep organs. The paper was read by Dr. Samuel West.

Dr. B. W. RICHARDSON read a paper on Pneumoparesis, which he defined as an acute form of disease usually confounded with pneumonia, in which the symptoms are due to sudden failure of nervous stimulus to the vascular pulmonary systems, nutritive and respiratory. After the recital of the cases, the author defined pneumoparesis as a progressive congestion of the minute pulmonary circulations with infiltration into the vesicular structure, ending in fatal cases by gradual asphyxia. Pneumoparesis is unattended by pyrexia, and is preceded by a distinctive train of nervous symptoms, consisting of emotional excitement, erythema fugax, extreme physical prostration, with short cough and little expectoration. The mind is impressed with the idea of impending death, but is neither alarmed nor anxious. There is no acute pain at any stage. The physical signs are dulness, commencing, as a rule, in the bases of the lungs, but sometimes in patches or centres, with fine crepitation at first, soon becoming moist, and in the later stages bronchial râles. The symptoms run a rapid course, and one that is usually fatal. If the organic nerves entering by the root of the lung could be divided, the phenomena witnessed would be those of pneumoparesis. Some years ago, by synthetical research, the author produced an artificial pneumoparesis in one of the lower animals, the rabbit, by placing it in an atmosphere charged with vapour of amyl nitrite, and he showed coloured drawings taken at the time of the condition of the lungs in different stages of the induced disease. In these cases the pulmonary paresis was caused by the action of a chemical substance on the organic nervous structures, and recovery followed upon the withdrawal of the cause, but the effects while they lasted were identical physically with those which had been described from the disease in the human subject. Pneumoparesis in the human subject, according to the author's view, is a disease having its seat in the organic nervous centres which in health regulate and control the pulmonary circulations. It is as yet an open point whether the failure commences in the nutritive circulation derived from the bronchial arteries rising from the thoracic aorta, or in the respiratory circulation of the pulmonary artery. This was a subject very rarely, if ever, studied, in relation to pulmonic affections, but it called for the minutest attention, especially in the disease now under consideration. On the whole, Dr. Richardson thought that in this instance the failure was first developed in the nutritive pulmonary vessels, and that the embarrassment in the respiratory circulation was secondary. Leaving this question as *sub judice*, he next spoke on the nature of the nervous lesion which led to the primary failure. This might be due *(a)* to mechanical injury, pressure or shock to the nervous-supplying centre or its plexuses; *(b)* to the generation within the body of some chemical product, which, like amyl nitrite, reduces to paresis the organic nervous supply; *(c)* to hereditary failure or premature exhaustion of the nervous-supplying centre under exhausting or depressing influences. The last-named view was that most favoured by the author, and we have only to let the mind become accustomed to the thought of the possible arrest of nervous stimulus in the pulmonary circulations as we do to other organs, and the fact of pneumoparesis is one of the most simple and clear forms of nervous failure and resultant structural lesion. But how wide a field it opens for observation. "Probably," Dr. Richardson said, "most of the aged or infirm die, as by natural anæsthesia, from pneumoparesis, under the added influence of cold, privation, fatigue, fear, grief, or some other temporary depressing cause." The treatment of pneumoparesis formed the concluding part of Dr. Richardson's paper. In this section he detailed the modes of treatment which had been followed in the cases under his observation. The treatment had been tentative in each case, for no rational and radical line of treatment had yet even been foreshadowed. In one case ergot was given, but without effect; in another the ammonia treatment had been employed with nux vomica, but with equal want of success. In the treatment of the third case, digitalis had been administered when the circulation was rapid, but it was impossible to say that it did any useful service; in fact, in spite of all treatment the symptoms ran an unbroken course. The record was discouraging; the "pathies" one and all were nowhere, and in short, in this as in many other instances, it would seem as if treatment receded just in proportion as a more precise knowledge of causation and cause advanced. The problem is clear, but how is it to be solved? The problem is: Given a condition in which the organic nervous supply of the pulmonary circulations is suppressed or exhausted from any cause, how shall the central failure be restored? In another case Dr. Richardson stated that he should administer oxygen by inhalation at 75° F., with the object of prolonging life and of giving time for a natural restoration of nervous balance; but even this would not be a radical cure, although in the right direction. Meanwhile he had fulfilled his present task if he had defined the disease pneumoparesis and drawn attention to a problem of cure which is most likely to be solved, *consilio animorum*,—

Dr. DOUGLAS POWELL said the cases reminded him of pneumonia without fever, and also of certain cases of bronchitis and pneumonia which terminated fatally from "drowning" of the pulmonary tissues by exudations and secretions into the ultimate air passages. In treatment strychnia and digitalis might be useful, and also the inhalation of oxygen, which he had used in a severe case of lividity with some apparent good effect.—Dr. C. H. ROUTH thought the cases resembled atelectasis pulmonum, and suggested that amyl nitrite and electricity might prove useful in treatment.—Dr. HUGHLINGS JACKSON remarked that he regarded acute pneumonia as a form of herpes zoster of the vagus nerve. Muscarine contracted the vessels of the lungs, and atropine antagonised this action, according to Brunton.—Dr. SAINSBURY spoke of the value of oxygen in diseases of the lung.—Dr. F. L. BENHAM considered the cases to be of pneumonic nature.—Dr. ANGEL MONEY was reminded by the cases of the rheumatic and other vaso-motor œdemas; he also held that there existed a mutual tension between peripheral and central organs, and this principle might be made available in suggesting rational treatment, as well as affording better views of the pathogenesis of disease.—Dr. THOROWGOOD spoke of cases of pulmonary engorgement of rapid onset, one of which was saved from a fatal issue by emetic doses of ipecacuanha.—Dr. SAMUEL WEST suggested myocarditis with heart failure and pulmonary thrombosis as possible recognisable causes of such symptoms as Dr. Richardson had described.—Dr. RICHARDSON, in reply, said amyl nitrite should not be used, and electricity was difficult, if not impossible, to apply rationally. He hoped to lay the subject of treatment by oxygen before the Society at a future date.

OPHTHALMOLOGICAL SOCIETY.

Unusual Complication after Subjunctival Tenotomy of the External Rectus.—Persistent Hæmorrhage in the Anterior Chamber after Iridectomy for Chronic Glaucoma.—Congenital Defect of External Ocular Muscles.

AN ordinary meeting of this Society was held on the 9th inst., Mr. J. W. Hulke, F.R.S., President, in the chair.

Dr. A. EMRYS-JONES (Manchester) read a paper on an Unusual Complication after Subjunctival Tenotomy of the External Rectus, relating to a girl aged ten, in whom both internal recti were divided for alternating convergent strabismus. Immediately after division of the left rectus there was profuse hæmorrhage into Tenon's capsule, leading to well-marked proptosis. A firm bandage was applied, and two hours later the proptosis was more marked, the pupil was widely dilated, inactive to light, and perception of light very doubtfult; the optic disc was very pale. From this time rapid improvement took place, and recovery was eventually complete.

Dr. EMRYS-JONES also read a case of Persistent Hæmorrhage in the Anterior Chamber after Iridectomy for Chronic Glaucoma. The patient was a man aged sixty-three, whose right eye was almost blind, and with + 1 tension; in the left eye, vision $\frac{6}{18}$, and the field of vision much contracted. The optic nerve was cupped. Iridectomy was performed on Oct. 24th, 1882. Free hæmorrhage followed, and the next day the anterior chamber was full of blood, and no trace of iris could be detected anywhere. There was scarcely any improvement in a fortnight. One month after operation the hæmorrhage had subsided considerably, and the outline of the pupil could be detected. The improvement was excessively slow, and it was not until Dec. 16th that an ophthalmoscopic examination could be made, when the vitreous was found to be clear and the optic nerve much cupped. There was cardiac disease, and the patient died on Jan. 17th, 1883, from double pneumonia. Mr. Haynes Walton had written something about this condition in his book when treating of injuries to the eye from mechanical causes.—The PRESIDENT asked what method of subconjunctival tenotomy had been employed in the first case, for he could not recall a similar accident. The hæmorrhage in the second case was persistent, and the blood retained its colour as in cases of diabetes.—Mr. ADAMS FROST had seen a similar accident to the first case.—Mr. ERNEST CLARKE had a similar experience, and thought it resulted from cutting too close to the sclerotic.—Mr. HULKE said Von Graefe intended that the tendon should be cut as close as possible to the globe of the eye.—Mr. LAWFORD had seen severe bleeding follow tenotomy, and give rise to proptosis and duskiness of the lids. A sudden effort on the part of the boy in whom the case occurred caused a fresh hæmorrhage, which subsequently subsided completely.—Dr. BRAILEY had seen similar accidents, and once optic nerve atrophy resulted therefrom. Perhaps there was rupture of one of the ciliary arteries, from too free use of the tenotomy hook. Von Graefe's operation was not likely to cause the accident.

Mr. LAWFORD read notes of four cases of Congenital and Hereditary Defect of Ocular Movements which had been under his care at St. Thomas's Hospital. These cases included a father and three of his seven children, the remaining four being unaffected. The three children who were the subjects of this congenital defect were Nos. 2, 4, and 7. In all four patients there were present the following symptoms—almost complete bilateral ptosis, loss of upward and downward movement of the eyeballs, and very defective lateral movement. Visual acuteness and accommodative power were good, and there were no ophthalmoscopic changes. None of the patients presented any other congenital defect, and they were healthy in every other respect. He referred to published records of similar cases, in some of which post-mortem examinations had been obtained, and drew attention to the fact that the ocular muscles, and not their nerves, were the structures at fault. These muscles had in some instances been absent; in others, though present, they were occasionally ill-developed, and generally shorter than the average measurement, while in almost every case their insertions into the sclerotic were displaced more or less backwards, the greatest degree of displacement being 2·5 mm.—The PRESIDENT said that it was difficult to say whether the muscles were primarily at fault, or whether there was defective innervation of muscles; disease in early life might produce such effects.—Mr. QUARRY SILCOCK supported the last idea, and related the case of a boy in whom the eyeball was not noticed to be fixed till the age of three years, and after a general illness which might have been infantile palsy, with a localisation in the eyeball muscles.—Mr. HENRY POWER spoke of the solidarity between nerve and muscle; the condition might be looked upon in some cases as a reversion to an earlier type; turtles and other reptiles had little movement, and perhaps some mammals might show an absence of the levator.—Dr. ANGEL MONEY objected to the principle of so-called reversion to an earlier type, and preferred to speak of an arrest of development.—Mr. BRAILEY said that the development of ocular muscles was not known; he did not think the reversion theory would hold good in the present instance.—Dr. SEYMOUR SHARKEY and Mr. DOYNE thought that the term reversion was a useful one.

The following living and card specimens were shown:—

Mr. SILCOCK showed a case of Exostosis arising from the Inner Side of the Orbit; sight had been early affected and was almost completely lost.—Mr. HULKE thought an explanation should be made; in one case in his own experience the tumour proved easy of removal.—Mr. HENRY POWER had had considerable difficulty in removing an exostosis from the roof of the orbit.—Mr. NETTLESHIP, in reply to Mr. Silcock, said the sight failed after the proptosis had been present one year.—Mr. SPENCER WATSON considered exploration would be necessary; but caution should be used not to employ too much force in chiselling, &c.

Mr. GUNN: A peculiar Foveal Reflex in connexion with amblyopia and myopia, so-called "policeman's lamp."

Mr. NETTLESHIP showed an ophthalmoscopic drawing from a case of Night-Blindness, with white dots scattered over the fundus.—A discussion followed relative to whether these spots were identical with those seen in Tay's choroiditis.

OBSTETRICAL SOCIETY OF LONDON.

Eclampsia of Pregnancy, and the state of the Renal Function.—Bright's Disease during Pregnancy.

A MEETING of the above Society was held on Wednesday, Dec. 7th, Dr. John Williams, President, in the chair.

Dr. GRAILY HEWITT showed a specimen of Columnar Epithelioma of the Cervix Uteri which he had removed by the écraseur.

Mr. G. M. BLUETT exhibited a specimen of Insertio Velamentosa. The cord was attached to the membranes about four inches from the nearest edge of the placenta.

A report was read on several tumours that had been shown

Digitized by Google

to the Society, Dr. John Williams' specimen was a pure fibroma, Mr. Meredith's was a fibro-myoma, and Mr. Malcolm's appeared to be a fibroma of the "youngest" type, including very new connective tissue.

Dr. HERMAN read a case of Eclampsia of Pregnancy, with observations on the state of the Renal Function. The author related a case of eclampsia coming on about the end of the seventh month of pregnancy. The patient recovered from the eclampsia, and the pregnancy continued for a fortnight afterwards, when labour spontaneously came on and a living child was born. During the lying-in period the patient twice had an erythematous rash, but except for this convalescence was undisturbed. The temperature during the eclampsia did not exceed 100°. The urine was daily collected, and examined quantitatively throughout. During the seizures it was small in quantity, of high density, but with a low percentage of urea, and containing much albumen. As the eclamptic seizures and the stupor following them passed off, first the percentage of urea rose, and then the quantity of urine and of total urinary solids ascended to the normal, and the quantity of albumen diminished. But the albuminuria did not disappear until after delivery; it sank from one-fifth before delivery to a trace on the third day after delivery, and disappeared on the sixteenth day. A slight increase in the albuminuria coincided with the erythema. The albumen was mainly paraglobulin. The author thought that the facts of the case tended to show that the disturbance in the renal function was due to altered pressure in the vessels, rather than to changes in the renal cells. The eclamptic symptoms subsided when only slight improvement in the renal function had taken place, which showed how large a margin of safety there was in the conditions under which the kidneys ordinarily worked. In an appendix, Dr. Herman communicated another case, which showed a similar alteration in the renal function—viz., during the eclamptic period a great decrease in the excreta of urea, not only absolute, but relative to the quantity of the urine and its specific gravity, the excretion of urea rapidly rising after the eclamptic symptoms had passed off.

Dr. HERMAN next read a case of Bright's Disease during Pregnancy. The author described a case of Bright's disease, manifested by œdema, headache, and albuminuric retinitis, occurring in pregnancy, and treated by the induction of labour in the eighth month of pregnancy, about seven weeks after the commencement of symptoms. The excretion of urea daily was measured during the weeks preceding and following delivery. The author compared the ascertained excretion of urea in this case with that in a case of eclampsia previously communicated by him to the Society, and showed that, in the case of Bright's disease without eclampsia, the amount of urea excreted, although below the normal, and below the amount excreted by the eclamptic patient after the disappearance of the eclamptic symptoms, was yet considerably larger than the amount excreted by the eclamptic patient at the time the symptoms of eclampsia were present. The author said that the view that "eclampsia is due to deficient excretion of urea, and the occurrence of eclampsia in a woman suffering from Bright's disease depends on the amount of urea excreted," was not a novel one. But it rested on inference, and had been little, if at all, supported by direct observation, because it was seldom that the opportunity for observation occurred in circumstances favourable for accuracy. These cases were evidence in support of that view. The author also called attention to the resemblance between the two cases in respect of the facts that the excretion of urea was larger during pregnancy than during the lying-in period, and that rapid diminution in the amount of albumen present in the urine followed delivery. He also drew attention to the different kinds of albumen present in the two cases: in the case of eclampsia (coming on in a subject who appeared to be previously healthy, and ending in complete recovery) the albumen was mainly paraglobulin; in the case of Bright's disease there was a copious precipitate of serum-albumen, but very little paraglobulin. This was in accordance with the views of Ralfe and of Maguire. In the case now reported, the Bright's disease was still present three months after delivery.

Dr. GALABIN thought that much light might be thrown by careful observations such as Dr. Herman's on the obscure points in the relation of puerperal convulsions to albuminuria. His own observations were in favour of the view that an essential element in the pathology of most cases of eclampsia is a poisoning of the nerve centres by the retention of products, not necessarily urea, through defective excreting power in the kidneys. Urea had been injected into the circulation of animals without ill effect; and in uric acid we had an example of a product much more scanty than urea, but capable in the human subject of producing more ill effects. Possibly there might be some still more poisonous substance among those present in very small quantity and now classed as extractives, the excretion of which failed when that of urea failed. He did not know what vascular condition of the kidneys Dr. Herman considered it to be which produced scanty excretion of water and was the cause of eclampsia. The only vascular condition which could produce such an effect would be one of low pressure and anæmia. He thought there was evidence to show that in many, if not all, cases of eclampsia the secreting cells of the kidney were affected as well as the circulation. 1. In fatal cases he had always found alteration of the cells evident on microscopic examination. 2. Although in many cases the albuminuria disappeared rapidly after delivery, this was not universally true. In about one-fourth of the cases he found that although the proportion of albumen rapidly diminished, yet a little remained so long as the patient was under observation. In one case he had found it persist nearly two years after eclampsia in a first pregnancy, yet the patient had recovered perfectly and went through subsequent labours without either albuminuria or eclampsia. It appeared that in some cases eclampsia was associated with Bright's disease, somewhat chronic in its after effects, but not necessarily incurable.—Dr. GRAILY HEWITT thought the remarkable frequency with which primiparæ suffered from eclampsia indicated that extreme tension of the abdominal contents in first pregnancies was an important factor. He had observed good results follow placing the patient so as to take off pressure of the uterus from the spinal region, and by procuring copious watery stools by means of compound jalap powder. Dr. Braxton Hicks had observed that sometimes albuminuria occurred first after the onset of eclampsia. Was it not probable that this albuminuria was the result of intra-abdominal tension from the spasmodic action of the abdominal muscles? He mentioned a case in which eclampsia occurred first after labour and ended fatally. One kidney was found the size of a walnut, and the other much diseased.—Dr. CLEVELAND thought that in puerperal eclampsia connected with defective elimination of urea, some decomposition of the urea took place before its toxic effect on the nervous system was manifested. In uræmic coma such decomposition was evidenced by the urinous or ammoniacal odour of the breath. He thought it of more importance to note the deficiency of urea than the presence of albumen in the urine. He would have liked some explanation of the mode in which pressure on the kidneys is said to produce eclampsia in primiparæ. He thought that in some cases there was sudden congestion of the organ, which impaired its eliminating function and produced albumen in the urine.—Dr. HANDFIELD-JONES thought that the disturbance of the renal function in eclampsia was often due to changes in the circulation of the kidney. He had met with a case in which normal urine was passed by the patient half an hour before delivery, and within three hours puerperal convulsions manifested themselves and bloody urine was passed, the urine becoming almost solid on boiling. This appeared to be due to vaso-motor disturbance, such as is met with in other regions.—Mr. JACOMB HOOD narrated two cases which he had seen lately. In the first the urine before delivery contained five-eighths albumen, and there was much œdema of the legs and abdomen. Labour was induced, and the patient did well until the sixth day, when she had convulsions for three hours and a half. Only a trace of albumen was found afterwards, and the patient was convalescent on the fourteenth day. In the second case, after the patient had been twelve hours in labour, blindness was complained of, and five minutes later strong convulsions ensued. The patient was delivered with forceps under chloroform, and after this there were six convulsions, and the patient did not recover consciousness for four hours after delivery. The urine was drawn off, and contained one-fifth albumen. On the fifth day after delivery there were three more convulsions, and the temperature rose to 101°. She was treated by free purgation and sweating, the latter by means of warm pack and pilocarpine. The albumen disappeared the day after delivery, but reappeared on the fifth day after

Digitized by Google

the convulsions. The sight gradually returned, and the patient was convalescent on the fifteenth day.—Dr. BOXALL said that in the majority, if not all, of the fatal cases of puerperal eclampsia which had come under his notice, the cortical portion of the kidney, if not diminished in area, was pale and anæmic, whereas the pyramids were congested, swollen, and standing up above the general surface of the section, and it seemed probable that the engorged bloodvessels of the pyramids lying between the tubules may exert pressure from outside to such an extent as to diminish the lumen of the straight or collecting tubules, and so prevent the free outward flow of fluid formed in the cortical portion, just as inflammation of the nipple offers an impediment to the escape of milk from the breast. He thought that congestion of the pyramids in association with anæmia of the cortical portion would appear to be sufficient to produce the variations observed in the urine.—Dr. PARAMORE thought that the impressionable nervous system was generally present in cases of eclampsia, which occurred so frequently in primiparæ, and when often in excellent health. For this reason he considered chloral and bromide of potassium were invaluable drugs in these cases.—Dr. HERMAN, in reply, agreed with Dr. Hewitt that we much needed information as to the typical course of puerperal eclampsia. This disease was so very acute, running its course within forty-eight hours, that extremely frequent observations were necessary in order to get a true picture of the phenomena. Eclampsia was not a common disease, and most cases could only be observed at the patient's homes, where very detailed and frequent record was impracticable. But for this consideration he should have waited till he could bring forward a larger number of cases. He did not attach so much weight as Dr. Galabin did to the objections made to the uræmic theory of the disease. Experiments on animals in which urea was injected into the blood without harm following he did not think conclusive, because the animals had healthy kidneys and could excrete the urea. He did not think that increased pressure within the abdomen was the sole casual condition, but he thought that the greater frequency of eclampsia in first pregnancies and at the end of pregnancy rendered it probable that pressure was one of the casual conditions, and this view was supported by the rapid diminution in the amount of albumen which almost always quickly followed delivery. Even if albuminuria persisted, there was generally a drop in the amount of the albumen. If the views of Ralfe and of Maguire as to the significance of the presence of paraglobulin and serum-albumen respectively in the urine should be shown by observation in a large number of cases to hold good, they would prove of great value in prognosis. He did not think that all cases of eclampsia were alike, for on post-mortem examination the renal changes met with were of the most various kinds: acute nephritis, large white kidney, granular kidney, dilatation of ureters and pelvis of kidney, were each met with, and in some cases there was no naked-eye appearance of kidney disease.

Notices of Books.

Dental Caries, and the Prevention of Dental Caries. By HENRY SEWILL, M.R.C.S. & L.D.S. Eng.—There are three different views of dental caries. In one the disease is assumed to be no disease whatever, but merely the result of chemical solution of the dental tissues, and therefore dependent both in its origin and its progress on the uncontrolled action of physical and chemical laws. Another hypothesis is that the teeth, being a part of a living organism, profoundly modify the progress of the disease; and a third, that caries is of inflammatory origin and comparable to caries of bone. Mr. Sewill gives a terse and lucid argument in favour of the purely passive condition of dentine during decay. He relies partly on the statement that caries will and often does take place in natural teeth mounted on artificial dentures or pivots, and that the naked-eye and microscopical changes are precisely similar to those seen in ordinary cases of teeth. On this point, however, there seems to be some discrepancy amongst observers. Tomes says that he has not seen a sufficient number of cases to be quite sure; Magitot, on the other hand, considers the "translucent zone" as characteristic of caries of living teeth. The fact that the dentine is evascular has often been used as an argument against its capability of inflaming—following the now exploded dictum, "where there are no bloodvessels there can be no inflammation." That some changes do take place in dentine during its disintegration is shown by various facts—the increase in sensibility, the hardening and pigmentation under favourable circumstances. Mr. Sewill gives some practical information about the prevention of caries with reference to constitutional and local treatment.

The Diagnosis and Treatment of Eczema. By TOM ROBINSON, M.D., L.R.C.P. Lond., M.R.C.S. Eng., Physician to and Lecturer at St. John's Hospital for Diseases of the Skin. London: J. & A. Churchill. 1887.—It appears in the dedication of this book that Dr. Robinson's chief objects in adding to the literature of eczema have been "to clear the ground of a number of words which are simply emblems of imagination," and "to connect together the morbid processes which we find occurring in the skin and mucous membrane, so that we may be enabled to peep through the veil and show that the causes of eczematous inflammation are identical with those that operate in all other forms of disease." Further he desires "to present the varied canvas of eczematous inflammation as an intelligible whole, to trace out the causes of this variety," and lastly to relieve suffering. However praiseworthy his objects and desires, we are sorry we cannot commend the work. There is little that is original, except perhaps the conception of the eczematous diathesis.

Lumley's Public Health Act. Annotated by WILLIAM PATCHETT, Q.C., and ALEX. MACMORRAN, M.A., Barrister-at-Law. Third Edition. London: Shaw and Sons. 1887.—The fact of the second edition of this work, which was only issued late in 1884, having for some time past been out of print, affords one of the best indications of the value that is set upon it. The present edition brings the legal aspect of public health up to current date, including as it does all the more recent statutes relating directly or indirectly to the subject. But the main value of the work attaches to the annotations to the several sections of the Acts dealt with, and the editors have evidently spared neither time nor pains in making these as complete as has been possible. Thus, in dealing with Sec. 157 of the Public Health Act, 1875, as to the making of bye-laws to control the construction of dwellings &c., they have covered no less than eight pages with matter that must be of the greatest value to those who are in any way concerned with the administration either of the law or of a code of bye-laws on this subject. The legal definition of the terms included in the statutes, the more important decisions that have been given on the subject, and the limits which are imposed on sanitary authorities in the matter, are all set forth. So also, in dealing with sections that relate to the prevention of the spread of infection, the same method is adopted, instances being cited to show the extent to which these clauses may be trusted by sanitary authorities and their officers in their endeavours to control infection. A considerable number of the original annotations have been modified or enlarged according as such circumstances as new legislation has rendered change imperative. The volume is necessarily bulky, for in order that it should in itself constitute a library of reference as to the statutes and decisions affecting public health, a copious index and a well-arranged table of cases are included within it; and it appears to us to be, without question, the most complete work relating to the subject with which it deals.

"Dead, yet Speaketh." By Doctor [illegible], Bristol: [illegible]-smith. London: Simpkin and Marshall. [illegible]

Digitized by Google

written by a physician in his leisure moments, of which, as a rule, members of our profession have not too many. Its interest centres in the close correspondence of unfolding events with the details of a vivid dream which is represented to have occurred to the narrator, and in which his friend, a young barrister, was seen to plunge a knife into the breast of an aged man at the instigation of the nephew of the victim, and in the presence of a sleeping girl of surpassing beauty, the prize to be won by the foul deed. The plot is simple enough, and the working out of its parts does not demand the exercise of a large amount of ingenuity. The *dénouement*, though making virtue triumphant, is, we think, somewhat abrupt and disappointing. One would like to find that villainy was not only defeated but adequately punished, whereas in this tale the villain simply drops out of view. Though two of the characters belong to the healing art, the story is refreshingly free from medical technicalities. The writing, too, displays in some places considerable power, and in others there are touches of quiet humour, as in the description of the bearing of different members of a country coroner's jury when about to engage in the momentous duty of "viewing the body." Spite of several indications of the prentice hand in the construction of the story, the book is very readable.

L'Ospedale Lina. Dott. Eduardo Salvia, Rendiconto Statistico. 1881-86.—The Lina Hospital was founded in Naples in 1880 by the Duchess Teresa Ravaschieri Fieschi for children. Dr. Salvia now publishes an account of the work done during the first quinquennial period of the hospital's existence. The total number of in-patients was 361, of whom a large proportion seem to have been admitted for surgical operations. Resection of bone and osteotomy were performed very frequently, considerable use being made of Macewen's osteotome. Forty-two children were operated on for vesical calculus, lateral perineal section being invariably the method selected. Of this number, three cases proved fatal—two from peritonitis and one from pneumonia. In all the cases chloroform was given, the operation was performed in the dorsal position, and Dupuytren's tube left in the wound.

An Index of Surgery, being a concise classification of the Main Facts and Theories of Surgery for the use of Senior Students and others. By C. B. Keetley, F.R.C.S., Senior Surgeon to the West-London Hospital. Fourth Edition. London: Smith, Elder, and Co. 1887.—The fact that a fourth edition of Keetley's Index of Surgery is called for is a sufficient proof of the favour with which it is regarded by "senior students and others." Only minor additions and alterations have been made in this edition, but they have been sufficient to keep it up to date, and to make it worthy of the reputation won by the earlier editions.

Précis du Cours d'Exploration Clinique et de Diagnostic Médical. Par le Dr. E. Spehl. Fasc. 1 to 3. Bruxelles et Paris: Lebegue and Cie.—Dr. Spehl is issuing in parts the text of his class instruction in practical medicine at the Brussels University. The three fasciculi before us include the substance of nearly three out of the twenty-four lectures of which the course consists. They contain a general description of clinical topography, the method of examination and interrogation of the patient, and the examination of the urine. There is nothing to call for special comment, for the character of such a work can hardly be estimated from such small instalments. A judgment will be formed better when the whole is completed. The scheme drawn up by the author seems to lack nothing in the way of detail.

Letts's Diaries, &c., published by Cassell and Co., offer a most complete supply of time-saving publications to meet the requirements entailed by the infinitely varied engagements and occupations of professional and commercial life, as well as of domestic economy. These diaries, date-books, wallets, &c., are all excellently got up, being securely bound to resist the effects of constant use the whole year round, while the fulness and intelligent arrangement of their contents leave nothing to be desired. With such aids to methodical work, negligence or slovenliness in its performance would seem to be wholly inexcusable.

METROPOLITAN HOSPITAL SUNDAY FUND.

The annual general meeting of the constituents of this Fund was held in the Old Council Chamber, Guildhall, on Monday last, under the presidency of the Lord Mayor.

The Lord Mayor, in opening the proceedings, congratulated the meeting on the circumstance that the past year had been the most successful in the history of the Fund, and expressed a hope that it would long continue its course of usefulness and benevolence.

Sir Sydney H. Waterlow said it could be well understood that it was a great gratification to him for the thirteenth time to propose the resolution asking their constituents to affirm and adopt the report which the Council had presented. The annual advance in the collection was a subject for congratulation. It had not been one continual progress, because that institution, like all others, whether founded for philanthropic, political, or social purposes, had its trials in the beginning. It had in its earlier years to win the confidence of the public and to make them feel that it supplied a want, and that the work that it undertook to perform was done honestly, conscientiously, faithfully, and usefully. The collection of 1887 was the largest that had been made, and the progress of the last six years had been very great. In 1874 the amount was £30,000, and in 1880 it had only reached £30,423—a very small percentage of increase; but it had since risen from £31,850 in 1881 to £40,607 in 1887, or 20 per cent., as against 2 per cent. in the previous six years. From 1874 to 1880 there was practically no increase in the number of congregations. Commencing with 1072, they rose only to 1225 in 1880, but in 1881 they rose to 1268, and in 1887 to 1633. (Cheers.) This showed that the work of the Fund progressed, and that ministers of all denominations were to an increasing extent coming to the conclusion that the best method of collecting money for the relief of the sick poor in their large hospitals and dispensaries was to do so on Hospital Sunday, seeing that by that means it would be collected and distributed at the smallest possible charge. Looking to the work that the Fund had to deal with, they found that in 1874 there were 104 institutions claiming to take a share of the funds collected. In 1887 there were 157 hospitals, dispensaries, cottage hospitals, and convalescent homes taking a share of the Fund—an increase of nearly 50 per cent. He did not mean to say that there had been fifty-three great hospitals established in London since 1873, but there had undoubtedly been many more convalescent homes, a class of institution that was growing into favour, and which the public had come to feel were an absolutely necessary adjunct to large hospitals. These convalescent homes had done more for the sick poor of the metropolis than even the hospitals themselves, for the hospitals never finished their work. They might cure a man of the acute evidences of disease, or by means of some operation he might be comparatively restored to health, but then he was often turned out in a condition in which he was unable to go back and win his bread, and he frequently broke down in endeavouring to do so. On the other hand, if they could send a man for three or four weeks to a convalescent home the work would be complete, the man gaining, with good food and good air, that strength which enabled him to become again the breadwinner of the family, from which by accident he had been taken away. (Cheers.) While the Fund had only increased 28 per cent., the number of institutions relieved had increased nearly 50 per cent. What he wished the public to understand was this: that, though they did not want more hospitals, they did want more money to enable the beds in existing hospitals to be utilised. (Cheers.) The first cost had been incurred; they had the hospitals, but many of them had not funds enough to admit as many patients as they had beds to accommodate. The great want of the present day was money to enable

Digitized by Google

them to fill the vacant beds, and it was one of the first Christian duties of the people each one to subscribe according to his means, however trifling, to accomplish that object. (Hear, hear.) One of the new branches of their work was setting apart a certain percentage of the money for the purchase of surgical appliances for the relief of persons who, having undergone all that hospitals and surgeons could do for them, required instruments, which the funds of hospitals, as a rule, could not purchase, and for which too frequently they had to apply to the general public. The Council of the Fund felt that this was a part of their work which ought not to go uncompleted. As matters at present stood, a duty of labour and pain was thrown upon the poor sufferers to which they ought not to be subjected—the duty of flying from one subscriber to another to get ten, twenty, or thirty tickets before they could receive the surgical appliance which they needed, too frequently causing an injury to the patient in the process of obtaining the instrument. The Council had deducted a certain percentage from the Fund during the last four or five years for this purpose. During the present year £1600 had been deducted, by means of which some 1500 persons had been relieved with instruments of various kinds, each costing from 5s. up to as much as £6 or £7. The patient had now no trouble except to go to the minister of the district in which he lived—Nonconformist or Church of England. The minister then sent the recommendation, and, if it was properly endorsed and certified, the secretary signed the order, which the patient presented at the nearest hospital or dispensary, and then obtained without further trouble the instrument necessary, fitted under the direction probably of the surgeon who treated the case. He ought not to close without referring again to the generosity shown by the late Dr. Wakley, who in the year 1886 gave them a donation of £1000. Dr. Wakley was deeply interested in the Fund, and no one perhaps was more competent to judge of its value than he, because he was the able editor and proprietor of THE LANCET, a journal dealing especially with the class which would bring all hospital matters under his own cognisance. Dr. Wakley gave them £1000, and he had by his will left them £1000, which had been paid during the past year. He referred to this as an evidence that the man most competent to judge felt that there was no charity in which his money would go so far as it would in the Hospital Sunday Fund for the relief of the sick poor of the metropolis. (Cheers.) He understood that some communication had been received from some of their friends referring to the fact that by their report and returns it was shown they did not contribute to some districts in London as much as they received from those districts. Certainly not. (Hear, hear.) How could the poor of the East-end contribute all that the wealthy denizens of the West-end could contribute? The establishment of the Fund was for the very purpose that the wealthy might contribute to the poor, and that the poor might receive the help of those who were able to afford it. (Hear, hear). He therefore hoped that contributors living in the West-end would feel that there had been a right appropriation of the money which they had given. They had also been asked whether they ought not to have a representative on the Council for each denomination. There were fifty clerical members of Council and 1633 contributing congregations. He understood that the denomination that had raised the question had four contributing congregations. They could not give a representative to every four congregations, seeing that the proportion of representatives to congregations was about 3 to every 100. The Fund was not administered with the slightest idea of anything sectarian. (Cheers.) They wished to make it a universal fund, and one of its great advantages was that it brought Christians of all denominations into harmony and union on the one day selected for Hospital Sunday. The universality of the Fund was one of its greatest recommendations. He begged to move, "That the report of the Council for the year 1887 is hereby received and approved."

The Rev. Dr. ALLON, in seconding the motion, said that Sir Sydney Waterlow was to be congratulated on the success of the Fund, which was the child of his own benevolent purpose. It was an object altogether apart from denominational considerations, and he protested against the introduction of such topics in connexion with the Fund.

Mr. T. NICHOLS asked whether any precaution was taken against the abuse of the charities assisted by the Fund. It was within his knowledge that there were many recipients of charity who were well able to pay small ordinary medical fees. He would suggest that after an applicant had once been relieved he should take away some form to be filled up, in order to prevent abuse.

Mr. READ contended that the Fund was not only a benefit to the poor, but to the rich, since they obtained the benefit of the large experience which hospitals afforded to medical men in regard to the different modes of medical treatment.

The motion was then agreed to.

Sir E. HAY CURRIE moved, "That the laws of the constitution which have been in force during the past year be continued." He said that they were all most grateful for what was done by the clergy and the congregations in aid of the Fund, but he hoped it would not be considered that £40,000 a year was anything like an adequate sum to be contributed by the wealth of London to such a purpose. Deducting the £1000 given by each of three large congregations and the £1000 legacy of Dr. Wakley, and dividing the balance between 1600 congregations, the amount contributed by each of them would be seen to be very small.

The Rev. RHODES BRISTOWE, in seconding the motion, expressed a hope that the practice of some churches of deducting from the hospital collection a certain amount for ordinary church expenses would be abandoned.

Mr. NELSON HARDY wished to draw attention to the manner in which the laws had worked in one particular direction. South London, which was more like the East-end than the West, and where the congregations were mainly poor ones, contained about one-fourth of the population of London, and it contributed about one-fourth of the total amount given to the Fund by the churches. But the entire amount given by the Fund for the treatment of the sick poor generally in South London (not including Greenwich Hospital, which was intended for particular classes) was £260. Adding the amount given to special hospitals and dispensaries, the total sum was £2696, as against £31,000 awarded to the rest of London, excluding in both cases convalescent hospitals. The result was that the hospitals of South London, so far as Hospital Sunday was concerned, were simply starved. Many poor patients had to go to hospitals north of the river, and their friends were thus put to unnecessary trouble and expense in going backwards and forwards. Hospitals like Guy's and St. Thomas's had not funds to accommodate all who applied, and many of the sick poor were finding their way into the workhouse infirmaries, where serious operations, such as ovariotomy, were now sometimes performed. It might be said that the hospitals in South London did not require help, but that was a mistake. Guy's, which formerly had an income of £40,000, had now only a steady income of £26,000; and the consequence was that 200 beds, which would be available for the treatment of the sick poor, were now empty.

Sir SYDNEY WATERLOW said that Guy's Hospital had been told that they could apply to the Fund if they liked, but they had declined to do so.

Mr. NELSON HARDY said that he had been informed by the treasurer that Guy's Hospital intended to apply next year. If, however, they were treated according to the existing laws, they would probably get so small an amount that it would be hardly worth while to apply. He thought, therefore, that a *primâ-facie* case had been made out for some inquiry into the working of the laws as they at present stood. He did not doubt that the laws had been admirably administered, but he would venture to move as an amendment, "That the laws as at present in operation be provisionally adopted, and that the attention of the Council be requested to the contrast between the receipts from South London churches and the awards to the South London hospitals and dispensaries, and that they be asked to consider what changes, if any, are desirable in the rules for the administration of the Fund."

The Rev. H. SWITHENBANK seconded the amendment. He said that he represented 5000 persons in the south of London, mainly poor people, and he was constantly sending sick persons to hospitals with recommendations from the Fund, but in almost every case they had to go across the water. He had no right of access to Guy's Hospital, though it was within easy distance.

Sir SYDNEY WATERLOW hoped that the meeting would not throw back upon the Council any question with regard to the appropriation of the money received in one locality to the wants of another. Any application from hospitals or dispensaries in the south of London would always be considered and justly dealt with. The treasurer of Guy's Hospital was told that he could apply to the Fund, subject to

Digitized by Google

the condition that their accounts were rendered in order that the Committee of Distribution might have the opportunity of investigating them, and determining whether upon its merits the hospital ought to receive a grant. When that condition was complied with, any application from Guy's Hospital would receive careful attention.

Mr. H. BURDETT said that the people in South London had relied upon the great endowed hospital of Guy's to provide all the necessary accommodation for the sick free of cost. They ought to be very careful before interfering with the present administration of the Fund, which had worked so well, and he hoped that the amendment would be withdrawn, or, if pressed, would not be carried.

Mr. A. L. COHEN said that, as a governor of Guy's Hospital, as well as a member of the Council, he thanked Mr. Nelson Hardy for his intervention, and he also thanked the Council, and Sir Sydney Waterlow in particular, for insisting upon an exact formulated statement of the accounts of the hospital. If twenty years ago its accounts had been overhauled by the critical eyes of the Council, very probably the hospital would not now be in its present plight. He trusted that it had turned the corner, and was getting into better order. He hoped, however, that Mr. Nelson Hardy would withdraw his amendment, and be content for the present with the useful discussion which had taken place with reference to it.

The Rev. J. R. SIMPSON expressed a hope that Mr. Cohen's suggestion would be adopted. He was quite sure that the matter would receive the best attention of the Council.

Mr. HARDY then withdrew his amendment, and the motion was agreed to.

The Rev. J. F. KITTO moved: "That the Council for the year 1888 be constituted as in 1887, with the following alterations—viz.: The Rev. S. B. Burnaby, M.A., in the place of the late Rev. Prebendary W. G. Humphry, B.D.; the Rev. the Hon. E. Carr-Glyn, M.A., in the place of the Rev. P. W. N. Bourne, M.A.; the Rev. Archd. Richardson, D.D., in the place of the Rev. R. Maguire, D.D.; Colonel Sir Reginald Hanson, Bart., LL.D., &c., in the place of the Right Hon. P. De Keyser, now Lord Mayor; Mr. Alderman Whitehead, in the place of the late Sir William McArthur, K.C.M.G.; Alfred L. Cohen, Esq., in the place of his late brother Lionel L. Cohen, Esq., M.P.; Claude Goldsmid-Montefiore, Esq., in the place of John G. Pitcairn, Esq.; and that the other retiring members be re-elected for 1888." He desired to echo the sentiment of Dr. Allon that anything like division into denominational parties should not be tolerated in the constituency. The real constituency of the Fund was the whole of London, and not any particular part of it.

Dr. HARE seconded the motion, which was agreed to.

On the motion of the Rev. C. J. RIDGEWAY, seconded by the Rev. M. BARLOW, it was resolved—"That the 10th day of June be fixed for Hospital Sunday of 1888, and that the cordial co-operation of all ministers of religion within the metropolitan area be again invited in the usual way."

On the motion of Dr. FORREST, seconded by Dr. GLOVER, a vote of thanks was passed to the Lord Mayor for presiding. His lordship having briefly acknowledged the compliment, the proceedings terminated.

ANNUAL REPORT OF THE MEDICAL OFFICER OF THE LOCAL GOVERNMENT BOARD.

[FIRST NOTICE.]

IN the recently issued annual report on the proceedings of the Medical Department of the Local Government Board Dr. Buchanan returns once more to the question of the diffusion of small-pox around metropolitan small-pox hospitals. Reading between the lines, it appears that his present remarks on the subject, and the great mass of materials which are embodied in a summary intended to show the more important data on which Mr. Power's conclusions were based, have been produced on the present occasion because of the insertion of Dr. Bridges' comments in last year's volume, and because of certain other criticisms which are held not to have been properly considered. It will be remembered that Dr. Bridges accepted the view that the hospitals did mischief, but he clung to the opinion that the evil was brought about by direct human communication, and not as the result of an aerial diffusion. We have often pointed out that this view can no longer be sustained, and, unless it could have been enforced on grounds that were in no way open to question, there certainly was nothing to justify an official suggestion that the official view of the Medical Department might, after all, be wrong. But the grounds alleged were weak in the extreme, and their publication has enabled Dr. Buchanan to express his view of them. Taking the principal criticism—namely, the circumstance that in one quadrant around the Fulham Hospital, containing 121 houses, no cases of small-pox were observed during an epidemic period of four months, a result which, it is implied, could hardly have been brought about if any aerial diffusion took place,—Dr. Buchanan retorts that his critic, who supports the direct communication theory, must have altogether forgotten the circumstance that the particular quadrant referred to actually contained the route and the only one by which all direct human communication with the hospital took place. Other criticisms of this aerial theory have been equally worthless, based as they have been, not on data as to the immediately surrounding population, but on statistical evidence as to the incidence of small-pox on registration districts.

Dealing with such critics, and especially with Dr. Bridges' memorandum, which was inserted at the President's request, Dr. Buchanan now asks his chief to allow him to request his future readers not to misrepresent him, or to hold him "incapable of seeing that what is true of five is presumably in a measure true of three or two, and so forth"; and he once more asserts that his department professes to have established a doctrine concerning the means of small-pox spread that is applicable for the practical purposes of the inhabitants of London, and that affords to hospital authorities, if they choose to recognise it, better opportunities than they before had of preventing the unquestioned danger incurred by those who live near to small-pox hospitals. The opportunities referred to, and especially the one which deals with a complete alteration in the system of small-pox construction, ought to be recognised. Much money has been spent on these hospitals; their method of administration has been modified to meet the views of the "direct human intercommunication" theory, but where small-pox aggregations take place the danger of diffusion still remains.

Typhus is another disease which has received a good deal of attention during the year reported on. It is a disease which, when once it gets a footing in a thickly crowded community, is most difficult to eradicate, and its appearance in 1886 naturally gave cause for anxiety. Some seventy districts were, in consequence, visited; and at the onset it became evident that many of the younger medical practitioners, including health officers, not having had experience of typhus, failed properly to diagnose the disease. Some gave the name of typhus to other forms of continued fever; and others, again, were unaware that they were dealing with typhus until it had spread fatally in their midst. In all, true typhus was found to be prevailing in seventeen important centres of population, its incidence being mainly in the most crowded and miserable localities; and it was in some instances discovered in precisely the same places that had been the scenes of its occurrence in past times. In many of these places it was necessary to point out anew that if sanitary authorities wish to keep their districts free from typhus, they must, above all, deal with the question of overcrowding, and be prepared in advance with such means of hospital isolation as shall enable them to place the first attacks under circumstances which will not constitute a danger to the community. There are few outbreaks that respond so easily to early and complete isolation as do those of typhus fever.

The whole subject of scarlet fever in connexion both with milk and with bovine disease is fully discussed in the report, but this subject is discussed in another part of our present issue.

The history of cholera during 1886 is also recorded in detail by way of supplement to the story told of the earlier parts of the epidemic of 1884-87 which has already appeared. And to this is added a final record of the cholera survey, which aimed at securing for places especially liable to cholera, either by reason of their position on the coast, or on account of known defects in their sanitary condition and administration, all such immunity as immediate measures of sanitary reform could be expected to provide. We have often referred to this survey, and we would again remark that though its details may be uninteresting, yet the principles underlying it are those which have tended so much to free this country from conditions favourable to the spread of cholera, and which have already brought about results which would have been impossible under a quarantine system.

THE LANCET.

LONDON: SATURDAY, DECEMBER 17, 1887.

THE interest excited by the etiological inquiry initiated by Mr. POWER and Dr. KLEIN, and completed by the researches of the latter, which have just been published in the 15th Annual Report of the Medical Officer to the Local Government Board, will be in no degree lessened by the report which was made on Thursday last to a special meeting of the Pathological Society by Professor CROOKSHANK, and which we publish in another column. Although we are unable this week to report the discussion at the Society, it may be well to direct attention to the question at issue between Professor CROOKSHANK and Dr. KLEIN, which forms so interesting a sequel to the original investigations. That inquiry, it will be remembered, commenced exactly two years ago, and resulted in the tracking of an epidemic of scarlet fever in North-West London, with painstaking care and conclusiveness, to a milk-farm at Hendon, and in the absence of any evidence of external contamination to the milk of certain cows suffering from an infective disease of the teats and udder. It is this "Hendon cow disease" that Professor CROOKSHANK states he has still further investigated, with somewhat remarkable result a result which does not confirm the notion of its scarlatinal nature. Yet it is well known how thoroughly Mr. POWER excluded every possible source of contamination of the milk before he came to the conclusion that the bovine and human disease were related. As to the cow disease, Dr. CAMERON analysed minutely its clinical characters, and declared it to be a specific contagious disorder differing from other somewhat similar affections to which the cow is liable; whilst Dr. KLEIN showed that the cutaneous and visceral lesions of the affection in inoculated animals presented a striking similarity to the lesions of scarlet fever. He succeeded further in discovering and isolating a micrococcus, the characters of which, upon cultivation, were perfectly distinctive, and by inoculation of cultures obtained ample evidence that the lesions referred to depended upon the presence of this microbe. His later researches were directed to human scarlet fever, and resulted in the detection of the same "micrococcus scarlatinæ" in the blood and tissues of patients. His inoculation experiments were numerous and all to the same purport, and he succeeded, both by inoculation and feeding with cultures of the micrococcus obtained from the human scarlatinal patient, in inducing a definite general disease in calves which bore a great resemblance to that observed in the Hendon cows. Thus it would seem as if the connexion between the human and bovine disease had been fully proved, wanting only the crucial but inadmissible test of human inoculation with the bovine virus—a test, by the way, which is equally inapplicable in the case of other infective diseases of the human species the bacterial origin of which is beyond dispute.

It was hardly to be expected that results so remarkable and far-reaching should have escaped criticism. They involved not merely the discovery of the scarlatinal contagium, but the implication of the most useful of domestic animals and most universal of articles of food in the propagation of the disease, to an extent which demanded very thorough investigation before acceptance. That milk is unfortunately a ready medium of contagion is proved by numberless instances of epidemics of typhoid fever, diphtheria, and scarlet fever traced to its use; but hitherto the milk-infection has been attributed to a human source. The result of Dr. KLEIN'S inquiry has then been to direct especial attention to the nature of the affection from which the cows at Hendon suffered; and to stimulate the Agricultural Department of the Privy Council to an inquiry of which Professor CROOKSHANK'S report forms the first fruit. Dr. THIN, in an able criticism upon the subject, delivered at the Dublin meeting of the British Medical Association, dwelt at length upon this side of the question, introducing new evidence from competent observers of the malady. He confirmed Dr. CAMERON'S statement that the affection is currently styled "cow-pox" by those who have the charge of the diseased animals; but neither Dr. THIN nor Dr. CAMERON considered it to be the true form of cow-pox, of which since JENNER'S day many counterfeits or spurious forms have been recognised. Indeed, Dr. CAMERON specially points out that in the Hendon cow disease there is neither a papular stage nor a subsequent pustule, and there is also an absence of such characteristic features of cow-pox as the central depression of the vesicle, marginal induration, areola, and ultimate pitting of the skin; in fact, in hardly any point did the two conditions approximate. In the light of Professor CROOKSHANK'S results, these statements are, it will be seen, of great importance, if only as showing the difficulties which JENNER must have encountered in his discovery of vaccination. The criticism of Dr. THIN and others extended beyond this point, and dealt with the evidence adduced by Dr. KLEIN from his bacteriological research. It may suffice here to say that this amounted to the suggestion that the micrococcus was nearly allied to streptococcus pyogenes, and was therefore probably the result of accidental contamination: whilst some thought that the conclusion of its scarlatinal nature had been too hastily arrived at. We need not dwell now upon the concurrent investigation by Drs. JAMIESON and EDINGTON into scarlet fever, and their discovery of a bacillus scarlatinæ; for, interesting as that line of inquiry is, it has no direct bearing upon the precise subject dealt with by Professor CROOKSHANK—viz., the relation of the Hendon Cow Disease to Scarlatina in Man.

Whatever value may be assigned to the pathological resemblances between the bovine and the human disease—and Dr. KLEIN has pointed out that the cutaneous and visceral lesions are very similar,—it cannot be contended that in their clinical features there is much similarity. In the cow a limited local eruption of highly contagious properties, with slight or no concomitant fever, can hardly be said to resemble the acutely febrile exanthematous malady in man. The characters of the cow disease appear to be definite enough, and Professor CROOKSHANK was requested to examine into examples of an affection which he identified with this disease. Nor did the grounds of identity rest solely upon the clinical phenomena. Pro-

Digitized by Google

fessor CROOKSHANK followed the same procedure as Dr. KLEIN, and by inoculations and cultivations arrived at the same results. He found the same micrococcus, as the cultures proved, which Dr. KLEIN had found in the Hendon cows and the scarlatinal patients; but the results of the post-mortem examination of the diseased animal are reported by Dr. KLEIN to be wholly different from the lesions he had previously observed. Then followed the investigation by Professors BROWN and CROOKSHANK of another and very extensive outbreak of the same disease, in which its locally contagious characters were extremely well hown, both in animals and in those who milked them. Inquiry, however, failed to reveal any cases of scarlet fever among the consumers of the milk from this large number of diseased animals. The question obviously turns upon the point whether the disease in this outbreak was the same as that first observed, and both similar to the Hendon cow disease; for although Professor CROOKSHANK does not state whether he isolated the streptococcus in this instance, he is evidently quite convinced himself of the identity of all these cases. The upshot of the inquiry is, however, most remarkable—sufficient to justify the unusual step of a special meeting of the Pathological Society; for, if all these cow affections are identical, this discovery would sever the chain of evidence adduced by Mr. POWER and Dr. KLEIN in support of their contention that the Hendon cow disease is scarlatina. It is not a fortnight since proof was afforded in the person of a farm lad, who had contracted it from the cow, that the disease observed by Professors BROWN and CROOKSHANK is indubitably cow-pox. Professor CROOKSHANK seems to have had suspicions of this as the inquiry progressed, and he evidently did not consider that the differences alluded to by Dr. CAMERON sufficed to separate the Hendon outbreak from true cow-pox. If Professor CROOKSHANK be right as to the identity of his cases and those at Hendon, as well as in the determination of their nature, then the current terminology of the farm has proved to be correct, in spite of the disclaimers of skilled scientific investigators; and the suggestion is forced on the mind that vaccinia in the present day is not so rare as has been imagined. At the same time it is highly improbable that the micrococcus which was discovered by Dr. KLEIN is the vaccine virus; for nothing can be plainer than the evidence he advanced in support of its existence in the blood and tissues of scarlatinal subjects. Professor CROOKSHANK promises further investigation on this point, but it is clear that he inclines to the view which Dr. THIN propounded that this microbe is a septic organism, and therefore only accidentally related to either cow-pox on the one hand, or scarlet fever on the other.

In the elaborate and exhaustive paper upon "Some of the Infectious Diseases common to Man and the Lower Animals," which he read before the Epidemiological Society on Wednesday, Dr. KLEIN devoted a considerable space to scarlet fever, and not only replied to such criticisms as those of Dr. THIN, but also by anticipation to the inquiry in which Professor CROOKSHANK has had a share. He pointed out that there were known to him seven kinds of streptococci, including S. pyogenes and S. scarlatinæ, which bore a close resemblance to one another in their growth, but which on careful study of the rate and mode of growth in various media could all be differentiated. One of these was the microbe yielded by the disease in the cow alleged to resemble the "Hendon cow disease." Dr. KLEIN stated that the only points of similarity between the two affections rested in the ulceration of the teats and udders. Professor BROWN had enabled him to make post-mortem examinations of some of the animals, and the result was an absence of the marked visceral lesions which had been found in the Hendon cows. Therefore he was not surprised that no cases of scarlet fever had been traced to the milk of the cows in the late outbreak. He also met the objection that the disease of the Hendon cows bears so little clinical resemblance to human scarlatina, by citing the instances of cow-pox and small-pox, of woolsorters' disease and malignant pustule, of scrofula and lupus and tuberculosis, in man and animals, as showing that diseases owning the same origin may assume different forms in different conditions. If, then, Dr. KLEIN be right, his opinion that scarlatina is one of the infectious diseases communicable to man still holds the field; but if Professor CROOKSHANK be right—and the vital importance of the subject requires that his conclusions should be thoroughly sifted—then the connexion between cow disease and scarlatina must of necessity fall to the ground, and the remarkable facts in support of the doctrine gathered in the first inquiry must be attributed to coincidence. The evidence adduced by Mr. POWER seemed irresistible in its logical sequence, and it is difficult to detect a fallacy anywhere in the chain of argument. We trust that the discussion at the Society, which is in progress as we go to press, will aid considerably in clearing up the question, which is of such moment to the community, and that more light will have been thrown upon the numerous vesicular diseases of the cow's udder which have been so long confused under the head of "cow-pox." In any case, it cannot but be useful that attention should be directed to the existence of these contagious diseases of the cow, so that every means may be adopted to prevent the spread of such disease in a herd or the dissemination of milk from infected animals.

IT has been said that typhoid fever has no geography. Its prevalence, no doubt, has a relation to heat, and there is more of it in tropical, semi-tropical, and temperate climates than in cold ones; still, allowing for differences of degree, it seems to prevail everywhere. Whether its causes are invariably the same in all countries may be, and is, a disputed point, but that it is a disease amenable to the operation of sanitary measures is wellnigh universally acknowledged. The deaths from this disease in England from 1861 to 1870 were at the rate of 19,000 per annum; whereas from 1871 to 1880 they fell to 7000 per annum; and at Frankfort-on-the-Main and at Dantzic we have statistical proof of the remarkable decline of this disease since the introduction of proper systems of sewerage and water-supply into those cities. Our attention has been called to this subject in connexion with a report thereon by the members of the Central Board of Health for the colony of Victoria, which has been presented to both Houses of Parliament by command of his Excellency the Governor. Typhoid fever is never altogether absent, but the colony has this year been visited by an epidemic. The same law

Digitized by Google

that holds good for England and America equally applies to Australia—viz., that typhoid fever chiefly prevails towards the end of the summer, and especially in autumn, and after periods of long drought. But the members of the Central Board of Health in their report rightly dwell on the fact that seasonal influence, after all, is merely an exciting, and not the originating, cause of typhoid fever. "It only co-operates with certain other auxiliary conditions which are favourable to the spread of the disease, but none nor all of these can in any true sense originate it." No subject has been more keenly discussed in recent times than the question of the causation of typhoid fever, with the practical outcome that it is considered an eminently preventable disease.

The members of the Central Board of Health of Victoria do not pretend to advance anything new in theory or pathology. They are content to accept the doctrines promulgated by some of the best minds of the medical profession in Europe and America, which BUDD very succinctly summed up in the words, "Contagion is the master-fact of its history"; and they proceed to explain and illustrate in what particular sense and through what instrumentality the contagium may exert its influence. As regards the extent to which the disease prevails in the colony, which can only be estimated approximately from the number of deaths, it appears that the mortality from typhoid fever in the colony last year was 522, the whole population being a very little over 1,000,000; and the mortality for the half-year, from January to June inclusive, for the present year amounts to 281 deaths in Melbourne and its suburbs alone. Dr. JAMIESON, contrasting Melbourne and its suburbs with the chief towns of England, shows that in 1879 the mortality from fever in twenty of the principal towns, including London, was at the rate of 2·9 per 10,000 of the population; whereas in Melbourne and its suburbs, on the average for ten years, it was at the rate of 7·3 per 10,000.

The Central Board calculates that on an average 3133 persons suffer from typhoid fever in Victoria every year, and that 470 of the cases end fatally; hence they are justified in sarcastically adding the remark that the disease has been very appropriately called "colonial fever." The Central Board then points out what are the "preventable causes," and how they can be "prevented." They first speak of the general apathy and ignorance that exist in regard to the subject, and under the head of "insanitary conditions" they enumerate various details with which our own experience in this country has rendered us familiar—such as improper disposal of nightsoil, contamination of water, milk infection, inaction of local boards, inadequate remuneration and inefficient action of local health officers, badly constructed dwelling-houses, and want of compulsory notification and power of isolation of contagious diseases. The members of the Central Board of Health wind up their sound and practical report by putting a few points prominently in the foreground as necessary to the effectual suppression of typhoid fever: compulsory notification, isolation, prompt removal by special service, destruction of typhoid excreta, general cleanliness, speedy abatement of nuisances, cleansing drains, abolishing cesspits, and protecting water-supply.

No uncertain sound pervaded the message given by Mr. FRANCIS GALTON in his recent popular lectures on Heredity and Nurture at South Kensington Museum. Strictly mathematical and logical throughout, he spoke forcibly out of the fulness of knowledge necessarily resulting from consideration of the life histories he has been collecting during so many years. The whole tendency of the thought actuating his work has been the accurate determination of future possibilities from the data afforded by the present condition. The accuracy of the forecast is, of course, open to question. When examining height, weight, or strength, as in testing mental power or knowledge by examination, we obtain merely an actual measure of the present condition, but we are hardly in a position to predict with certainty what will be the future outcome of that condition. The most that can be said is that the individual possesses so many units of strength, knowledge, &c., and from these his "class place," as compared with other individuals under similar conditions of age, &c., can be readily ascertained. The value is entirely of present limitation. All experience shows that, however soothing a knowledge of our present state may be, yet humanity will never rest satisfied with this, but will press for a prognosis. The three dimensions of life measurement are the past, the present, and the future; of these, undoubtedly the one of greatest interest is that which has yet to be revealed, and it forms a subject of endless speculation, since it necessarily possesses an element of uncertainty. So far as our individual future is concerned, Mr. GALTON'S measurements fail to be of very much help; they may determine the quantity, quality, or nature of work that can be performed, estimating the "output" of the machine, and so preventing the twofold waste of latent power and of useless struggle; they may serve as a guide for the healthy development of the young; they may determine the relative position of the individual, class, or nation—that is, they may inform us whether we are living in an age of progress or retrogression; but even while indicating the lines along which progress or retrogression is taking place, they can obviously take no count of the future variations likely to ensue from so-called "chance" external circumstances. They cannot predict that the powers which are latent shall ever be employed; they cannot ensure the continued development of strength or of mental faculties. External circumstances must constantly arise capable of damping the ardour of youthful aspirations, and thus cramping and limiting the "output." The disturbing influences at work to overthrow all calculations are by no means overlooked by Mr. GALTON; but when all is said and done, we have still to make the individual application of a general law, and it is precisely here that the doctrine of averages fails to give very much comfort. The statement that one in seven dies of consumption may not disturb the equanimity of a healthy man, but will fill a hypochondriac with dismay. The sick are very apt to take a pessimistic view of their own ailments, and it is impossible to reassure by statistics which merely record a low rate of mortality. It may be a matter of curiosity to know the probable heights of our future sons and daughters, but this interest will be lost upon those who realise that they have no prospect of a family. In other words, while doctrines of averages may be, and undoubtedly are, correct when estimated from a consideration of a sufficiently large number of facts, they can be of very little value in isolated cases. For purposes

Digitized by Google

of treatment, every case has to be studied, not merely as belonging to a special class, but for its definite characteristics, which render rational therapeutics something higher and better than a mere record of symptoms to be met by particular drugs. If this were the be-all and end-all of medicine, a carefully compiled dictionary of symptoms and treatment might with safety be placed in the hands of any intelligent but uneducated member of the laity. Statistics have a certain value which we would not venture to deny, but observations of classes will never supersede in value or importance the observation of the individual.

Mr. GALTON has avowedly no concern with existing disease; he looks rather to the future chances of disease, and he estimates these mainly from the family history and the personal condition. These two elements represent the past and the present out of which the future is to be built. If his facts can be proved, and there appears to be no loop-hole for disproof, then there cannot be two opinions as to the validity of his conclusions. He aims at the improvement of the human race by what might be termed the judicious choice of parents. Considering what he calls the enormous "output" of babies per annum, this is certainly a question worth considering. *Eugenism* (meaning goodness in birth and in rearing) is essentially to be desired. By public opinion much can doubtless be done to promote *eugenism*, if the public can only be sufficiently educated to recognise and desire the best means of forwarding such high aims. But this is not the whole battle. Excuses will always be made for special instances of unwise marriages, even though the probable issue may be doomed to serious disadvantages, which can be estimated, from a business point of view, by the extra premium ordinarily demanded by assurance offices when one or other parent has been the subject of disease such as phthisis. Mr. GALTON spoke warmly on this question, perhaps the only aspect of the case he could conveniently present to a mixed audience. Every medical man has probably been consulted about the propriety of marriage under other conditions in which there is a fair prospect of the sins of the fathers being carried as a curse to the next generation. Responsibility presses heavily upon medical practitioners when the results of undue complaisance may be so extremely disastrous. None the less, however, have such questions to be faced boldly; and if, as Mr. GALTON remarked, the pulpit is silent upon the physical influence of one generation upon the next, it is but right to demand speech from those who know the vast importance of the subject in all its bearings. Sanitation is good, and will, we hope, tend to the general improvement of the human race. Gymnastic exercises, when properly controlled and reasonably practised, will also develop capabilities which are but too often stunted and allowed to degenerate as a side condition of our civilised life in large towns. But above and beyond both of these, we cannot too clearly emphasise the national importance of means of checking ill-assorted marriages of persons afflicted or threatened with hereditary complaints. Such marriages too often result from gross ignorance of their probable consequences, and the lesson for the medical profession to take seriously to heart is the need for individual boldness on their part in warning patients of their almost criminal folly at the very time when they may expect congratulations. It will demand self-sacrifice on their part to realise the full bearings of their sad inheritance, and to avoid contributing to the sum of sickness and misery in the world. Our course, however, is clear, and may readily be gauged by consideration of our duties in times of epidemics, when our prime object, the arrest of the spread of disease, shines brightly before us. Knowing, as we do, that certain physical conditions will all but inevitably be transmitted in the event of marriage, we ought not to avoid any occasion of speaking firmly and forcibly to prevent the production of a sickly race.

THERE has been no more satisfactory meeting of the friends of the Hospital Sunday Fund than that of Monday in the Guildhall, under the presidency of the Lord Mayor, of which a full report appears at pp. 1225 to 1227. This is the real testing meeting of the year, in which the Fund takes its rise *de novo*. The Council is created for a year only, and the laws are enacted for a similarly definite time. Unless the consenting churches should see fit to renew their benevolent organisation in favour of the Fund, the whole machinery of Council, laws, and collection would collapse, and with it the £40,000 or so that go to reinforce the scanty coffers of our metropolitan hospitals. The meeting of Monday was not a meeting of the Council, but of the constituency which creates the Council and regulates its action. To this meeting representatives of all the contributing congregations are admitted, and it is on this occasion that any delicate or burning question which affects hospitals, or which exercises the public mind in relation to them, is apt to arise. One or two such questions were raised at the meeting on Tuesday, and disposed of with much good sense and good temper. One of these had reference to the precautions taken by hospitals to prevent the abuse of their charity by persons capable of paying ordinary medical charges The answer of Sir SYDNEY WATERLOW was that this was rather a question for individual hospitals than for the Council of the Hospital Sunday Fund, although it was one to the importance of which the Council was not insensible; also, that with regard to any matters of doubt in the administration or merits of hospitals, the Council had the power, which it frequently used, of asking interviews with managers. Mr. NELSON HARDY raised a question, which he had previously alluded to in our columns, as to the disproportion of the sum raised for the Fund in certain parts of London to that distributed to the hospitals of the same part. The point had been also mooted at one of the summer meetings of the Fund prior to Hospital Sunday, and was properly relegated to the constituents' meeting. Mr. HARDY'S speech was all that could be desired. It was a clear and good-tempered statement of the fact that South London gives more to the Fund than it receives. It gives well on to a quarter of the Fund, and it gets back again for its hospitals and dispensaries little more than a twelfth. The speech of the seconder of the motion, the Rev. H. S. SWITHENBANK, was equally reasonable. Both he and Mr. HARDY declared that in consequence of the Council not giving a grant to Guy's grave cases on the south side of the river had to be treated in the Poor-law infirmaries, or recommendations had to be asked from the Council for hospitals at a distance—

Digitized by Google

a practice which was injurious to the patients. The meeting was so satisfied with the working of the existing laws of distribution that it declined to modify them. But Mr. HARDY expressed himself quite satisfied with an assurance given, on the suggestion of the Rev. Mr. SIMPSON, that the case of Guy's, with its 200 vacant beds and diminished rent roll from agricultural depression, should receive the earnest consideration of the Council. It was not a little remarkable that even Mr. COHEN, a governor of Guy's, while grateful to Mr. HARDY, entirely approved the decision of the Council, and expressed the hope that by careful management Guy's would be able still to preserve its independence—an independence on which it and South London generally are to be congratulated. It cannot be too often repeated that the south of London has been greatly favoured by two largely endowed hospitals, and that the generosity of GUY, who lived more than a century since, has left wealthy men of that district free to distribute their liberality more widely. What is now wanted is a wide imitation of the munificence of GUY on the part of those having or leaving great sums of money. Out of such heaps hospitals should be greatly favoured until every empty bed and vacant ward is filled with the victims of suffering whom hospital rest and skill might restore to comparative health. Small subscriptions are not to be despised, and it is to be hoped that the Hospital Sunday Fund will yet grow to larger proportions, as it has lately increased. It must be remembered that private generosity has in this country to do what is done in other countries by the State or by municipal rates. We cannot more opportunely recall this fact than at the present time, and in a month of winter when the rich and the poor meet together, and when the rich have no pleasure greater than that of mitigating the miseries of poverty, especially when they are emphasised by those of disabling sickness. The Council of the Hospital Sunday Fund is again charged with the high duty of receiving and distributing a great collection, and we wish for it every success, not only on Hospital Sunday, but as a medium of large gifts and legacies to one of the best of all causes.

Annotations.

"Ne quid nimis."

THE ATTEMPT TO POPULARISE MEDICINE.

IT is satisfactory to know that the arguments which have been brought forward in THE LANCET during the past few weeks to combat an ill-considered attempt to teach to all and sundry the "dangerous little" of medical treatment have not been used in vain. That endeavour we then described, and we still regard, as being charged with a power of incalculable injury to the general public whom it presumed to instruct. It ignored entirely what constitutes the very core and essence of accurate and safe practice—the cardinal principle that personal examination and skilled diagnosis are as absolutely essential to the successful use of remedial measures as the remedies themselves. They are, indeed, even more essential, for though a given form of treatment, as expressed in drugs and the like, may be dispensed with and substituted by some other, the fundamental principles which distinguish between the proper and improper use of all such remedies cannot be thus lightly used. They are incorporated with every detail of practice, and requiring as they do, for a just understanding of their significance, a sound knowledge of all the sciences subsidiary to medicine and of medicine itself, it is impossible that they can be duly appreciated or applied by any man save the trained and qualified medical practitioner. We have therefore no hesitation in condemning as hostile to the well-being of the lay population, as it is obstructive to the better purposes of judicious practitioners, the effort of more than one cheap semi-medical journal to secure a credulous public against the need of medical attendance by offering it such fruitless half knowledge as can be communicated through the popular press. It is, we assert, as we have already said in a former issue, impossible to treat the serious responsibilities of practice as if they were mere accessories to general education. Medicine is, probably without exception, the calling for which an accurate and lengthy professional training is absolutely indispensable in order to justify its practical application. It is not to be merely read up from a book or learned from popular lectures. It is no mere joinery or smith's work with tools and material—no matter of common shrewdness or business capacity such as the mind of any capable and industrious man may compass. It deals with structures the most delicate, highly organised, and sensitive, which the mind of the Creator has contrived, with tissues rendered interdependent and intersensitive by the most intricate anatomical and physiological relations. Above all, it takes in hand the great question of life and death, and assumes the high privilege of determining the course of disease. Is all this to be lightly committed to a body of unqualified laymen, simply on the ground that they can read and think? Yet this is the real issue of the late new departure in popular medical journalism. We would not at all fetter the free exercise of opinion in the matter, but would only ask that judgment may be allowed a voice in the minds of those who possess it. Meantime, we think we may congratulate the medical profession on the ground which has been taken up by the great majority of its members on this question. In particular, we feel that the action of the Royal College of Surgeons at its last meeting, when this matter was discussed, calls for universal commendation. On that occasion the decision of the College was shortly given in the following terms: "Resolved that, in the opinion of the Council of the Royal College of Surgeons, it is most objectionable that Fellows and Members of the College should allow their names to be advertised in connexion with medical or surgical subjects in popular journals." We, and at the same the public generally, are thus assured that, whatever misunderstanding has deceived some gentlemen connected with the College as to the practical result of the attempt to supply a popular version of the principles or practice of medicine, in whole or in part the representative members of their body have not been parties to the same error.

DR. KLEIN ON DISEASES OF MAN AND THE LOWER ANIMALS.

THERE was a large gathering of members and visitors at the Epidemiological Society on the 14th inst., to hear Dr. Klein's paper upon "Some of the Infectious Diseases common to Man and the Lower Animals." It was, as the President, Dr. Thorne, remarked, a masterly production, and although of unusual length, it was attentively followed by the meeting. The diseases described by Dr. Klein included cow-pox, foot-and-mouth disease, hydrophobia, glanders, diphtheria, actinomycosis, anthrax, tuberculosis, and scarlet fever, and specimens in illustration of the various microbes of these diseases and their cultures were exhibited. A few points in the paper can only now be alluded to. As to cow-pox, Dr. Klein mentioned the difficulties of its production

Digitized by Google

by variolous inoculation of the cow, and explained these difficulties by the suggestion that if cow-pox be modified variola, then such artificial inoculation was not the right way to infect the animal, but that the virus should be introduced by the respiratory and digestive tracts. Similarly, foot-and-mouth disease, which is transmissible by contact, and indirectly through milk, is very difficult to inoculate artificially. As to hydrophobia, he pointed out that the conditions of Pasteur's prophylactic were not yet fully determined, that in animals subcutaneous inoculations were variable, and that a material factor in the way of obtaining definite results in man is the wide range of the incubative period, which may bear some relation to the intensity of the virus. The instances of transmission of diphtheria from animals were characterised as being very contradictory; but the bacteriology of glanders and actinomycosis was shown to be fully determined. As to anthrax, the dangers arising from the exposure of the bacilli to the air, when they give rise to the spores whose resistance is so marked a feature, were fully pointed out, and the precautions to be taken to prevent the spread of the disease from infected carcases were detailed. Dr. Klein also showed that when human beings are infected by the bacillus itself the result is a local disease—malignant pustule; but when by the spores, which gain entrance through the respiratory and digestive tracts, the result is mycosis intestinalis, or a general infection, such as is seen in woolsorters' disease. The differences between bovine and human tuberculosis were shown to rest not only in the distribution of the anatomical lesions, but in the size of the bacilli and their distribution in the tissues, as well as in the comparatively greater virulence of bovine tubercle as compared with human, on inoculation of rabbits and guinea-pigs. Such differences may, however, only be due to the difference in the environment of the bacillus; and although there was no direct evidence of the transmission of the disease by the consumption of flesh or milk of infected animals, he thought it safer to reject the use of such a food supply. Allusion was also made to fowl tuberculosis, and the practical reminder given that birds so infected were often well nourished, and therefore liable to be sent to the market. The tubercular nature of scrofula and lupus was held to be conclusively settled. Coming to scarlet fever, Dr. Klein briefly referred to the evidence which had led to the discovery of the micrococcus scarlatinæ in the Hendon cow disease, and said that, when all the evidence was known, critics would be not quite so positive as they had been. He dealt at some length with Dr. Thin's criticisms, which he did not think were based upon sound data; and, as stated elsewhere, declared that the characters of a cow disease now under investigation, which had been affirmed to be the same as the Hendon cow disease, differed from it in many essentials. He referred also to Dr. Edington's discovery of a bacillus, which he maintained could not be held to be proved until the microbe had been found in the circulating blood—e.g., in the heart — before the third day of the attack, and also in the cutis before desquamation. He knew of five different septic bacilli which resembled in their characters the Edinburgh bacillus, and yet had never detected the latter in any of his numerous investigations into scarlet fever. The etiology of this disease was extremely difficult, and no criticism or researches into it should be shunned; only it ought to be made without prejudice, and in a scientific spirit. Prof. Brown, in moving a vote of thanks to Dr. Klein, repudiated the notion that in their inquiries there was any antagonism between the two Governmental departments, and instanced how on this, as on many occasions, each department had sought and received the aid of the other. Professor Axe seconded the vote, which was carried by acclamation. The debate was then adjourned on the motion of Sir J. Fayrer, seconded by Dr. Buchanan, and it was announced that it would be opened at the next meeting by Professor Brown.

THE LATE SIR GEORGE BURROWS.

SIR GEORGE BURROWS, M.D., F.R.S., Hon. Fellow of Caius College, Cambridge, Physician in Ordinary to Her Majesty the Queen, and Consulting Physician to St. Bartholomew's Hospital, died at an early hour on the 12th inst., in his eighty-seventh year. Sir George, after receiving his early education at Ealing, attended for two years the lectures of John Abernethy at St. Bartholomew's Hospital, and at the end of that time proceeded to Caius College, Cambridge, where he obtained a Tancred Medical Studentship and graduated as tenth wrangler in the Mathematical Tripos of 1825. He was elected a Fellow of his College, and Junior Mathematical Lecturer. He afterwards returned to St. Bartholomew's, and having qualified, studied his profession for some time at the University of Pavia, in Paris, and in Germany. During his stay in Italy he had abundant opportunities for watching the epidemic of Asiatic cholera, then freshly imported into Europe; and upon its making its appearance in London in the year 1832, he was placed in charge of the auxiliary hospital established by the governors of St. Bartholomew's to meet the exigencies of the outbreak. This was his first official connexion with the institution. A little later, in 1834, he was appointed the first assistant physician, to take charge of out-patients, and was associated with Dr. P. M. Latham as joint lecturer on the Science and Practice of Medicine. In 1841, upon Dr. Latham's enforced withdrawal from ill-health, he became sole lecturer, and was promoted to the full physiciancy, an office which he held till 1863, when he retired from the acting staff and was elected the first honorary consulting physician. At the Royal College of Physicians he was nominated for all the principal lectureships, and filled in turn the offices of member of Council, Censor, College representative on the General Medical Council, and, finally, with the unanimous voice of the Fellows, President of the College. During his tenure of office as President — namely, in 1874 — he was made a baronet. Having been appointed Physician Extraordinary to Her Majesty the Queen in 1870, he became Physician in Ordinary in 1873, on the death of Sir H. Holland. He was a member of the Senate of the University of London, and President of the General Medical Council, and of the Royal Medico-Chirurgical Society, and of the British Medical Association.

TYPHOID FEVER IN FRENCH AND ENGLISH TOWNS.

BEYOND a general impression that typhoid fever is very generally prevalent in France, no official statistics showing the actual mortality from this disease in different parts of that country were, till quite recently, available. The monthly bulletin, "Statistique Sanitaire des Villes de France," which is now issued by the Public Health Bureau of the Department of Commerce and Industry, gives precise information of the monthly mortality from this disease in each of the fifty-one French towns having a population of 30,000 persons or upwards. It will be interesting to compare the mortality from typhoid fever in these French towns with that recorded in the twenty-eight large English towns dealt with in the Registrar-General's Weekly Return. During the three months of July, August, and September last, the deaths from typhoid fever in the fifty-one French towns above mentioned were reported to be 1342, and equal to an annual rate of 0·86 per 1000 of their population. Now, in the twenty-eight large English towns the death-rate during the same period from "fever" (including besides typhoid fever, typhus, and ill-defined forms of fever) did not exceed 0·23 per 1000 of the estimated population, the highest

Digitized by Google

rates in the several towns being 0·41 in Birkenhead, 0·50 in Salford, 0·63 in Preston, and 0·64 in Portsmouth. Let us now consider, in greater detail, the death-rates from this disease in the French towns. The rates in the four largest towns were 0·58 in Paris (against 0·17 in London), 0·46 in Lyons, 2·31 in Marseilles, and 0·60 in Bordeaux; the mean rate in these four towns was 0·76, against 0·86 in the whole of the fifty-one towns, showing that the mortality from this disease was not so high in the four largest as it was in the other large French towns. If we calculate and compare the rates from typhoid fever in these smaller towns, we find some remarkably high rates. In Havre, with a stated population of 111,277, the deaths from typhoid fever were 39 in July, 108 in August, and 110 in September, or 257 in the third quarter of this year; this gives an annual rate of 9·24 per 1000 of the population. The annual rate during these three months was 1·62 in Rouen, 2·24 in Montpellier, 2·79 in Angoulême, and 2·27 in Avignon. Judged by this sensitive standard—the death-rate from typhoid fever—it is evident that the sanitary condition of a large number of the French towns, other than the largest towns, is eminently unsatisfactory. There is, however, every reason to hope that the publication of this monthly health-bulletin will serve to stimulate public interest in France in health matters, which would inevitably lead to sanitary progress, now so much needed.

THE TIME IT TAKES TO THINK.

MEN in all ages have been familiar with the fact that thought is habitually more active and more speedy in the case of some persons than of others. Whether in the exercise of the imaginative or the reasoning faculty, or in the action of that guiding purpose of life which we call the will, the general truth of this observation has been always evident. As we come to a higher stage in human development, with its corresponding increase of intelligence, it is not remarkable that the mind should seek to subject itself to a closer scrutiny, and to catalogue more exactly the results of its introspection. This has happened with regard to the question before us. In particular has the period which intervenes between the impact of impressions from without and the visible response of the will in muscular action or other mode of expression become of late years a subject of careful investigation. Since the first quarter of the present century, when the comparative speed of visual observation was chronicled in the case of the astronomers Bessel and Struve, the varying rate at which the mind responds to the numerous impulses which reach it from the outer world has been measured with some exactitude. Most of our readers are familiar with the term "reaction" period. They will recognise it as expressive of the whole interval between the action of a stimulus, of whatever kind, and the visible response of the individual affected by it. They will also perceive in the period of "reduced reaction" that interval shortened by the space of time allotted by experimental precision to the transit of purely sensory and motor impulses — the period, namely, which changes the one into the other, and represents in the mind the average time required to think and to will. Discoveries not now very recent have taught us that the ordinary duration of this period is, in the case of simple impressions, about one-tenth of a second, and that where the impression is rendered complex by affording the mind a choice of sources to which it may be referred, the time required is increased by about another tenth of a second. An equally interesting side of the subject, however, is that which exhibits the force of impressions as modifying the rapidity with which they are accepted and, in familiar phrase, digested by the mental centres before they are visibly transformed into action. The rapidly energising power of sudden fear, joy, hope, and desire is thus explained. So likewise the contrary effect of some of these emotions may be explained as being due to a stunning effect produced by the causes which give rise to them upon the mental centres. It is also manifest that the energy of the mental reaction must largely depend upon the reserve of force in those centres at the time of activity. They must not be overtaxed by prior stimulation and excessive use; if their response is to be a vigorous one, they must be well nourished and have seasonable rest. There is therefore, even in these psychological minutiæ, a moral for the times—namely, that if we would preserve our mental efficiency amid the changing pressure of circumstances, we must by occasional recreation withdraw the mind from too continuous application.

SMALL-POX AT LEICESTER.

SINCE last week another of the persons reported as being placed in quarantine has developed a mild attack of small-pox, making the seventh member of the family who has contracted the disease. With the exception of the youngest, all were vaccinated, and all these six have had an attack of the mildest description. One other case has occurred in the town, this being a young man who had visited the infected house, and as he was one of those who had been under daily observation he was removed to hospital upon the earliest appearance of the disease. This patient had been vaccinated, and the attack is a very mild one. On Saturday, Dec. 10th, another case was discovered just outside the limits of the borough, and this patient was promptly removed to the small-pox hospital, and his wife and four children placed in quarantine wards. This man appears to have contracted the disease at Sheffield. On the 14th yet another case, a man, was discovered in the same district of the borough as that in which the former cases occurred, though the connexion between these several attacks has not been traced. Ten cases are now in hospital. Owing to the almost entire absence of infantile vaccination in the town, some little difficulty was experienced in promptly obtaining vaccine lymph for the revaccination of those whom it was deemed advisable to revaccinate.

ACUTE THYROIDITIS.

THE thyroid gland may be the seat of an acute inflammatory enlargement running a definite course without suppuration and terminating in perfect recovery. In these clinical characters we find a resemblance to ordinary mumps. Dr. Barlow read a paper on "Acute Enlargement of the Thyroid Gland" at the last meeting of the Clinical Society, and he related the case of a little boy, aged three, in whose thyroid gland an attack of inflammation occurred, which lasted altogether about a fortnight. The child had just previously suffered from erythema nodosum on the legs, and it was whilst recovering from this affection, and after having been out in the park, that the thyroid enlargement commenced in association with a nasal catarrh, of which the chief symptom was a discharge of thin glairy mucus. Reviewing the literature of the subject, Dr. Barlow arrived at the conclusion that his case must be regarded as coming under the "idiopathic" class of Lucæ, and although there had been erythema nodosum, still the absence of arthritis and heart disease or other genuine rheumatic manifestations formed a warranty for not considering the case as of true rheumatic nature. Some observers, chiefly abroad, have noted a rheumatic swelling of the thyroid having a definite relationship with well-founded rheumatism; and Dr. Angel Money quoted a case of this character from his own experience. Mr. James Berry narrated many interesting particulars concerning acute enlargement of the thyroid gland; and some of these having a fatal ending might tally with cases like the one narrated

Digitized by Google

by Dr. Barlow, in which the enlargement at one time had a threatening aspect. Nevertheless, the definite cycle run by cases of rheumatic and idiopathic descriptions must, we think, be held to differentiate them from ordinary goitre, in which the mode of commencement may be acute, but the course always chronic, and showing recurrent tendencies. The perusal of Dr. Barlow's paper will raise the reflection that the causation of acute thyroid enlargement is as imperfectly known as it is seemingly various.

CONSTRUCTION OF THEATRES.

IT is a hopeful sign that the Royal Institute of British Architects has devoted an evening to the discussion of the important subject of the construction of theatres. The construction of theatres must be similar in principle to that of all buildings devoted to large public gatherings, and, as the right of public meeting is just now much exercised by the British public, the proper construction of the rooms in which these meetings are held is of paramount importance from the treble point of view of convenience, health, and safety. Mr. Ralph Nevill, who furnished the paper upon which the subsequent discussion was based, seems to have given much thought to his subject, and many of the points upon which he touched were treated with marked ability. As far as the question of convenience is concerned, Mr. Nevill rightly insisted that the triangular form, with the stage at the apex, was best, as affording an uninterrupted view to each member of the audience. The little matter of placing the seats in the stalls alternately, so that the persons in the back row can see between those in the row in front, is from the point of view of comfort most important. The remarks as to the dangers of long straight staircases were certainly true, and it should be the aim of architects to lessen the length of staircase as much as possible. It is probable that in case of panic from fire there is less danger in ascending an easy gradient than in descending. The importance of this point is very great, but we do not notice that Mr. Nevill touched upon it in the course of his paper. We are glad to see that Mr. Nevill recognises the fact that, although the electric light does not foul the air of the theatre to the same extent as gas, it does not assist in the ventilation as the latter illuminant can be made to do. The admission of fresh air and the outlet of foul air, are, after all, the most important points in the construction of theatres, and we are convinced that the draughts, which are the chief characteristic of the modern theatre, are certainly due to the fact that architects do not attack this point with sufficient courage, and the air not being admitted in sufficient quantity in the right places, it must rush through the wrong ones and thus cause draughts.

WHAT CONSTITUTES COMPETITION AFTER THE SALE OF A PRACTICE?

MR. JUSTICE CHITTY has just delivered judgment in a case of dispute between the buyer and seller of a practice concerning the subsequent attendance of patients within the prescribed area by the vendor, who, notwithstanding that the agreement which he signed contained a clause providing that he should not "in any manner whatsoever, directly or indirectly, enter into competition with" the purchaser, thought that so long as he did not solicit practice he had still a right to attend any of his old patients who might desire it. In support of this view, it was stated that these patients preferred him to the purchaser, and that, indeed, they would not have sent for the latter, who was the plaintiff in the action, under any circumstances, so that he really lost nothing, and the defendant, the vendor, had not entered into competition with him. To this the judge very properly remarked that, though these patients might have preferred the defendant to the plaintiff, it was impossible for anyone to say that under no conceivable circumstances would he send for a particular medical man, also that the competition, if not active and direct, was indirect, and was thus of a kind which was definitely excluded by the covenant contained in the agreement. This view was strengthened by the existence of a peculiar clause in the agreement, by which the vendor was entitled to retain certain patients whose names were specially marked in a list, and consequently by inference he was prohibited from retaining any others. Judgment with costs was given for the plaintiff—i.e., the purchaser,—and an injunction issued to restrain the vendor from infringing any more upon his rights.

MENTAL AFFECTIONS AND AURAL DISEASE.

SUFFERERS from noises in the ears are sometimes greatly distressed by the tinnitus, and cases of suicide have been ascribed to sheer desperation resulting from an inability to get relief from the everlasting noise. Ménière's disease and some cases of epilepsy are attributed to disease in the ear setting up changes in the central nervous system. The question is still unanswered whether actual mental disease, mania or melancholy, may not be produced by aural disease, apart from any annoyance due to tinnitus or deafness. Coarse diseases, such as otorrhœa, suppuration in the mastoid cells, perforations of the drum, polypi, waxy concretions and foreign bodies, are easy of recognition and can be appropriately treated generally by simple surgical methods. But nervous affections due to irradiation from the obscure aural mischief are not always so open to treatment, because the changes in the ear are more subtle, but none the less real. Sometimes an obstruction of the Eustachian tube may be the chief cause of tinnitus, owing to unpoised atmospheric pressure leading to excitation of the labyrinth and acoustic nerve by actual compression. M. Boucheron believes that, besides vertigo, epilepsy, and other nerve troubles, mental disease may be originated, and simple inflation of the middle ear has been followed by a cure.

"ARSENIC CANCER."

As the mind is naturally caught by the curious and by the threatening, so we cannot avoid alluding to the subject which Mr. Jonathan Hutchinson raised at the last meeting of the Pathological Society. We fear, however, that at present further light is required before our knowledge can be considered satisfactory. Many amongst us having a strong belief in the efficacy of arsenic know well its power to produce disease; but, judged from the discussion at the Pathological Society, some do not appreciate the influence of arsenic on the skin. The skin *par excellence* is the tissue on which arsenic has perhaps its most marked influence; besides improving, it may spoil the complexion, rendering it muddy and unsightly. This latter action is also manifested in all parts of the skin, and may lead to the development of soft corns, not warts, in the palms of the hand and soles of the feet, where a roughened condition also grows up under the influence of this most potent drug. So far Mr. Jonathan Hutchinson goes with safe step on sure ground, but the next move onwards towards the belief that arsenic can produce epithelial cancer is less secure. It cannot be said outright that arsenic may be the chief cause of epithelial cancer, but we think the position almost impregnable if it be maintained, as, indeed, Sir James Paget and Mr. Hutchinson strongly held, that arsenic may prove one of the causes of epithelial cancer in certain constitutions. Nevertheless, arsenic will not fall into disrepute, for

Digitized by Google

at the worst it is only when continued for many years in very full doses that the drug is alleged to have so deleterious an action. Such a revelation, if it ever comes, will only make medical practitioners more careful in prescribing arsenic.

FEVER IN LONDON.

SCARLET FEVER is continuing to decrease in London, and the Metropolitan Asylums Board's hospitals are relieved of the pressure of the last few weeks. The Board may therefore look forward to a period of comparative rest during the early months of next year, unless circumstances should show the necessity for them to provide for some other malady than that which has recently taxed their resources. Expressions of approval have been during the last week bestowed by the press upon the Managers for the energy they have shown in extending their accommodation in proportion to the demands made upon it, and it must be admitted that these encomiums have been well deserved. Londoners have chosen to treat cases of scarlet fever in hospital, and the only Board which could undertake this duty has freely exercised its powers to meet their requirements. At the same time, the London Fever Hospital, which is largely dependent upon the support of a charitable public, has been supplementing the work of the Metropolitan Asylums Board by providing for patients of a somewhat higher social grade than those which usually seek admission into the hospitals of the Managers. Small-pox shows a tendency to obtain a footing in the eastern districts of London, and during last week one person suffering from this disease was removed to hospital from Bethnal-green, and two from Poplar. The amount of prevalence of enteric fever remains much the same, fifteen cases having been removed during the week. Typhus has again appeared, a lad aged sixteen developing this disease in the district of Limehouse. Hitherto the character of the weather has not favoured the production of typhus, and it may be hoped that the comparative absence of the disease from London up to the present time augurs that the winter will pass without any special prevalence.

THE FATALITY OF TIGHT-LACING.

IN our issue of June 25th we drew attention to the abuse of tight-lacing, which possesses for many wearers of the corset such a fatal attraction. Shortly before that date an inquest held upon the body of an elderly female revealed the fact that death had resulted from this practice. Only a few days ago a nearly similar instance was recorded. In this case, a young lady who suffered from fatty infiltration of the heart died suddenly while dressing hastily after a hearty meal. Here also tight-lacing played a prominent part in determining the fatal result. We had hoped that sensible reflection upon the bad effects of this injurious custom, as illustrated in the history of a former generation, might have impressed upon the would-be fashionable the obvious teaching of experience. The cases just quoted, however, are probably but a representative minimum of a larger number which do not come before the coroner's court, and the evil they exemplify, though certainly less general than of yore, still continues to act as a potent cause of ill-health. It is hardly necessary to repeat at length the causes which render this abuse of the corset so effectively mischievous. Pathologists have a clear perception of all that is implied in its doubtfully graceful discomfort. The displacement of almost all the organs in the chest and abdomen, the compression of several of these upon the heart and great vessels, and the restriction of breathing space which is thus entailed, have in their eyes no beauty, but the sad aspect of feebleness wilfully acquired, with the promise of a lifetime as brief as it is practically useless.

HEREDITY AND NURTURE.

IN his third and concluding lecture at South Kensington, Mr. Galton dealt with the influences of various kinds of nurture, training, and occupation on the average vigour, longevity, and disposition of large classes of persons. He considered that the surroundings influence future generations rather than the present. With a diagram he indicated the relative proportions of early and late marriages in Germany, England, and European Russia, showing the enormous preponderance of late marriages in the first, and of early marriages in the last; considering that, when other things are equal, early marriages are followed by large families, he led up to the amusing conclusion that the "output" of Russian babies reached a thousand a day. From Dr. Ogle's report upon the death-rates of varying ranks, he illustrated his remark that the quality of stock varies with the status of the parents. He then proceeded to the unforeseen and wide consequences of apparently small reforms, instancing the smallness of families in France since the law regulating the equal division of property. In strong terms he then dealt with the prevailing want of statistical imagination and our consequent carelessness as to undoubted social duties, considering that the marriages of phthisical persons should be prevented by public opinion, if not by more stringent measures. He thought that obvious sanitary neglect should be treated as manslaughter, and that legal restraint should check the pursuit of any line of conduct whose average ill effect has been ascertained. In approving terms he referred to the establishment of professorships of physical culture at Amherst and Harvard Colleges in America, and quoted from a correspondent at Wellington the opinion that the "cultivation of man as a whole, and not only in part," should be encouraged by the bestowal of degrees. In New Zealand it would appear that a prize has already been awarded to the "best-made man." Of the value of gymnasia in the hands of medical men rather than of professional athletes, and of the importance of more rigid school hygiene, he also spoke enthusiastically. In conclusion, he gave a brief retrospect indicating his belief in the theoretical possibility of raising the standard of the race by a study of the influences that tend to *eugenism*, a word implying goodness in birth and in rearing.

THE CASE OF LINNELL.

THE death of Linnell, which took place at Charing-cross Hospital, was the result of pyæmia, consequent on a compound fracture of the femur into the knee joint. The injury was sustained during the Trafalgar-square demonstration of Nov. 20th. The coroner's jury found "that there was nothing to show how the fracture was caused," and considering the conflict of testimony given at the Court, this portion of their verdict commends itself to one's approval. Several witnesses deposed that the deceased never varied his statement that the injury was caused by a fall, whilst others asserted that he attributed it to a furious charge of the mounted police. As regards the discrepancies in the medical evidence, we must note that the post-mortem examinations were made at different dates, and, considering the changes likely to occur in tissues affected by injury and disease, the various statements may be reconciled. That a compound fracture of the femur, in which the soft tissues must have been extensively lacerated, should be accompanied by the appearances of bruising is only natural, and we hold that it might be extremely difficult to determine the ultimate cause of the bruises. There was certainly nothing in the medical evidence to convince us that the bruises were produced by the kick of a horse, although a fracture of the femur implicating the knee joint was more likely to have been caused by direct than by indirect

Digitized by Google

violence. The coroner exercised a wise discretion when he decided to close the inquest with the evidence before him, for it is not likely that further medical investigation would have thrown additional light on the case.

SMALL-POX IN THE PROVINCES.

WE are now approaching the period when, in the ordinary course of events, an epidemic prevalence of small-pox may be expected. In most of our former outbreaks the provinces have suffered subsequently to the metropolis, but this winter a number of small-pox centres have been established in various parts of the country. The epidemic in Sheffield has acquired very serious proportions, and it has become diffused in many instances around the borough. The guardians of adjoining unions have, however, established special conveniences for vaccination, and it is to be hoped that these may aid in staying further diffusion of the disease. In November 180 fresh cases were admitted into the Winter-street Hospital, and the Corporation are complaining that the Local Government Board do not, with sufficient promptitude, aid them in establishing a separate temporary small-pox hospital in a more isolated position. Loans for such purposes cannot be obtained except after a certain statutory interval for notices and a public inquiry, and even if there has been no other or unnecessary delay, this alone must prevent hospitals erected in an emergency from being ready for an existing epidemic. The fact is, that to all having recent information as to the behaviour of urban small-pox hospitals it has been obvious that the borough infectious hospital in Sheffield was a wrong place for the aggregation of small-pox, and it is a pity that this fact was not faced before the present urgency arose. Apart from Sheffield, suspicious occurrences of small-pox have taken place in many parts of the provinces, the South Yorkshire colliery districts being specially implicated. But in the neighbourhood of Bristol a substantial and serious epidemic is in progress. Barton-Regis seems to have been first affected, and the authorities unfortunately attempted to deal with it by means of the very imperfect arrangements existing at the workhouse, the result being a most unfortunate spread amongst the unhappy inmates of the union house Then the authorities took in cases from Bedminster, which made matters worse; and at the present moment they appear to be at their wits' ends to know what to do. We trust the true lesson may be learnt—namely, that accommodation for small-pox amongst all classes must be of a special character, unless sanitary authorities want to diffuse the disease by aggregation of the sick. So far, 105 known cases have occurred within the city and county of Bristol, and the Corporation are doing what they can, by isolation and otherwise, to grapple with the disease.

ALLEGED CASE OF DIPHTHERIA IN A DISSECTING ROOM.

SOME little excitement has been caused in Lyons by the death of a medical student from diphtheria, which, according to the newspapers, he contracted from a subject he had been engaged in dissecting. To this assertion the dean of the Faculty wrote a distinct denial, stating that the bodies of patients dead of diphtheria are never sent to the dissecting room. This, however, did not satisfy everybody, for a rejoinder appeared, signed "A group of *externes*," declaring that the child whose body had been dissected had died of croup. According to *La Province Médicale* the cause of death was meningitis. Though the practitioner who sent the case to the hospital had diagnosed it as one of diphtheria, the house physician had been unable to find any evidence of diphtheria, and the little patient died the same night that it was admitted. Even if the child had had diphtheria, *La Province Médicale* thinks it is extremely doubtful whether the theory of infection could be maintained, for it is not by any means certain that dead diphtheritic membrane can convey infection, especially after the lapse of eight or nine days, which was the period that had intervened between death and dissection. In addition to this, the unfortunate student had not touched the thorax or throat, having been engaged merely with the brain.

THE HOT-AIR BATH IN THE TREATMENT OF ANTHRAX.

IN the course of a prolonged coroner's inquiry into a fatal case of woolsorters' disease, which occurred recently at Bradford, Dr. Bell, who had charge of the patient, stated that he had him removed to the infirmary in order that the treatment by hot-air baths might be satisfactorily carried out. This line of treatment is based on the fact that the bacilli anthracis are destroyed at a high temperature. Dr. Bell stated, in reply to questions by the coroner, that if a case were sufficiently early treated by hot-air baths there would be good hope of recovery; indeed, in the case in question he was unable to cultivate the bacilli found in the blood, and concluded that they had been killed. With respect to this point, it has been shown by Davaine and others that the development and spore-producing power of the bacillus anthracis is hindered at a lower temperature than will actually kill the adult microbe. Davaine found that non-diluted anthrax blood required subjection to a temperature of 51° C. (123·8 F.) for a quarter of an hour before it lost its virulence; but Dr. Bell's statements indicate that a much lower temperature will suffice—viz., 107° or 108° F.

NURSES.

NURSES have good reason to believe that their calling and their class are looking up. There is perhaps a little fear of their being too much "nursed," and we are not surprised to see indications that they are conscious of this risk, and showing a desire to be a little more independent. There certainly is now a large number of women with sound knowledge of nursing work and of what is wanted to place the workers in a sound and satisfactory position before the public; and it would seem well that, if nurses are to be educated and organised, they should debate the question of their own education and organisation with as little interference as possible. We presume it is with some such views that a number of ladies met on Wednesday, Dec. 7th, on the invitation of Mrs. Bedford Fenwick, late matron at St. Bartholomew's Hospital, to discuss the advisability of forming an association for the mutual help of all women engaged in nursing the sick and for the advancement generally of their professional usefulness, both to medical men and the public. The representative nature of this movement may be gathered from the list we publish in another column of ladies who have consented to act on an executive committee of a British Nurses' Association, which it was resolved to form. It is premature to express a definite opinion on the views of the matrons and others assembled at the residence of Mrs. Bedford Fenwick, but they may confidently rely on the support of the profession in any well-conceived plan for raising the education and status of nurses. Nobody can be satisfied with the existing state of things. Many of the present nurses, though immensely more efficient than their predecessors, are still inadequately trained, and show strange limitations of knowledge and education even in their peculiar work. The public are ready to pay, and are actually paying, considerable sums for professional nurses, and it is only fair that nurses should be able to provide guarantees of efficiency. A short time ago we commented on the importance

Digitized by Google

attached to nursing in American cities. In almost all of these a register of nurses is kept, and in most cases a two years' hospital training is required as a condition of admission to the register. There is an extensive feeling that some such system of registration must be established here. At the meeting of ladies on the 7th inst. a feeling was expressed that the training must be real, and must be more prolonged than in many of our nurse-training institutions. The object of these ladies, indeed, is to command the respect of the medical profession, and through it of the public. There is reason to believe that they have already secured the support of many leaders in the profession. It is probable, however, that both the question of nurses and of midwives will soon have to be considered by the Legislature, and that some authoritative medical body must have legal power to deal with them in the public interest. We hail the meeting referred to above as a sign that we shall soon have an organised system for the education and certification of nurses.

BACTERIOLOGY OF SMALL-POX.

PROFESSOR J. HLAVA describes in the *Sbornik Lekarsky*, a Bohemian medical journal, the results of some microscopical and bacteriological researches he has lately made on the contents of variolous pustules and the blood and viscera of small-pox patients. In four out of five cases streptococcus pyogenes was found in the blood and viscera. In the skin and in the pustular contents there were found, in addition, staphylococcus albus, saccharomyces (Proteus Zenkeri), and staphylococcus citreus cereus. The identity of the micro-organisms found with pyogenic microbes was demonstrated experimentally, but none of them produced small-pox. Professor Hlava believes that the variolous poison produces characteristic changes in the epithelium of the skin, and that in consequence of these pyogenic cocci invade the dermis, being carried thither by the circulation, which they enter through abrasions of the surface of the pharynx and larynx, which, he says, are invariably to be met with in small-pox patients. Thus variola would appear to be, in the majority of cases, a disease due to a mixture of infections, variolous and pyogenic, the latter class of infection entering the body subsequently to the former.

COMPENSATION FOR DEFECTIVE DRAINAGE.

DAMAGES for injury brought about by defective sanitary states of dwellings are by no means common, and for this reason alone it is worth recording that towards the close of last month £100 were awarded as compensation to a gentleman who had lost his daughter by reason of the defective drainage of the house he occupied. We are not aware of the particular circumstances of this case, but as a general principle we think that the responsibilities of landlords who seek to make gain by letting houses which are, in point of health, unfit for human habitation need to be strongly pressed home; and every such case as the above aids in this direction.

STRANGE INCIDENT AT CORDOVA.

LAST week Dr. Middleton of Scarborough, who was on his way to Tangier, halted with his companions at Cordova. Leaving his fellow travellers at the hotel, Dr. Middleton, accompanied as a guide by a gipsy, visited the cathedral, than which there are few more attractive buildings in the world, for when Cordova was the capital of the Moorish realm in Spain it was the great mosque of the city. He had begun to descend the narrow winding staircase of the tower, followed by the gipsy, when suddenly the latter attacked him from behind, nearly strangling him with one arm, while with the other hand he took two dollars from his intended victim's pocket, and wrenched his walking stick away. Dr. Middleton then drew his revolver and fired two shots over his shoulder, one of which entered the gipsy's mouth, the other taking a downward course through his body. The shots were fatal, and, covered with blood, Dr. Middleton descended and gave notice of the occurrence to the police, who, on their arrival at the scene of the tragedy, found the dead thief still holding in his hand the stick and the dollars. Dr. Middleton was arrested, but has since been released on bail. The gipsy had, it appears, the worst of reputations, and a most significant fact is that he was companion two years ago to an Englishman visiting the cathedral tower, who was found dead at its foot. The case was then supposed to be one of suicide, but, looked at in the light of Dr. Middleton's experience, it is now viewed differently.

THE PORT OF LONDON.

DR. COLLINGRIDGE reports favourably on the health of the port of London during the first half of this year, and although cholera has been again prevalent on the Continent, no cases were found amongst the shipping. He is evidently profoundly discontented with the action which is being taken by the Metropolitan Board of Works professedly to deal with the nuisance arising from the filth-laden river, and he declares that any so-called deodorisation of the sewage must be useless in the absence of precipitation. Referring to the isolation of the infectious sick, he rightly regards it as an anomaly that the Public Health Act should enforce removal to hospital for preventing the spread of disease to others, and yet make it permissible to charge the patient for the cost of his maintenance in hospital. Hence he advocates the abolition of all such payments, whether from the sick or the masters of vessels.

DONDERS MEMORIAL FUND.

AT the last meeting of the Ophthalmological Society a report was read from the Council recommending the appointment of a committee of its members to act in agreement with delegates of other scientific societies in establishing a "Donders Memorial Fund" in this country. The object of this fund is to assist in commemorating in some way the name of Professor Donders, who has done so much for biological science and ophthalmology; and the occasion chosen is his necessary resignation of his chair in the Utrecht University on attaining his seventieth birthday. The committee appointed by the Society consists of Mr. J. W. Hulke (president), Dr. W. M. Ord (treasurer), Messrs. Seymour G. Sharkey and R. Marcus Gunn (secretaries), Messrs. Jonathan Hutchinson, Henry Power, and W. A. Brailey, with power to add to their number.

TYPHOID FEVER IN YORK.

THE city of York has now for some time past had a certain notoriety in connexion with an excess of typhoid fever, and according to Mr. North, the medical officer of health, there were during the third quarter of this year just twice the number of attacks that prevailed during the corresponding period of last year. It is now long since Sir John Simon wrote on typhoid fever as the typical filth disease, and this recurring excess of the disease in York is unquestionably associated with an excess of filth about the houses of the Yorkshire city. Indeed, referring to both typhoid fever and diarrhœa, Mr. North plainly tells his sanitary authority that they must choose between the abolition of foul middens, privies, and filth receptacles on the one hand, and the infliction of periodic attacks of these diseases on the other. It is to be hoped that the York public will themselves so far appreciate the importance of the subject as to place on

Digitized by Google

their Town Council those who object to the retention of antiquated methods of fouling the air about houses, and who will do all they can to maintain a higher standard of health among the community whom they represent. In the meantime a committee has been formed to ascertain the results of action already taken in other large towns to remedy similar evils.

PORTRAIT OF SIR WILLIAM JENNER, BART., K.C.B.

WE are enabled to state that the sum already subscribed will more than meet the expense of the portrait and the two replicas, one of which is to be presented to the Royal College of Physicians, and the other to University College, to which Sir William Jenner was for many years physician. The committee purpose to keep open the subscription list a short time longer, and should the surplus at their disposal prove sufficient, it is their intention to have the portrait engraved and to present a copy of the engraving to each subscriber The treasurers are Charles J. Hare, M.D., 15, Manchester-square, and George Pollock, Esq., 36, Grosvenor-street.

ALEXANDER'S OPERATION IN BELGIUM.

DR. THIRIAR of Brussels, in a note in *La Clinique*, records the case of a lady who, having prolapsus uteri, and being unable to wear pessaries, as they always occasioned a good deal of suffering, willingly accepted the proposal of Alexander's operation of shortening the round ligaments. This was accomplished without serious difficulty, rigorous antiseptic precautions being taken; but Dr. Thiriar, finding the resistance to traction considerable, thought it wise to limit the shortening to about five centimetres, though Alexander mentions ten to twelve centimetres as being the amount to be aimed at. The patient made an excellent recovery, being catheterised regularly at first, and being kept strictly in a recumbent posture for three weeks. Dr. Thiriar mentions that this operation was first proposed and practised on the cadaver by a Belgian surgeon, Professor Deneffe of Ghent, in 1864, who made one abortive attempt to perform it on the living subject. It was not till 1881 that Dr. Alexander proved its feasibility.

THE COMPULSORY NOTIFICATION OF INFECTIOUS DISEASES.

THE Town Council of Wigan are seeking powers from the Local Government Board to borrow money for the purpose of building a new infectious disease hospital, or, as some of the members of the sanitary committee are pleased to call it, a "sanatorium." At the same time, in the same provisional order, they seek powers "to alter and amend the Wigan Improvement Acts of 1874 and 1880, enabling the corporation to make bye-laws compelling the notification of infectious disease within the borough, or otherwise enforcing such notification." This clause caused some discussion in the council chamber last week, because it was felt by some members to be "interfering with the liberty of the subject," and by others that it should not be rushed through without ample discussion by the ratepayers, and that also information should be sought from other towns as to the working of compulsory clauses. It was, however, decided, by fourteen votes to ten, that the corporation should go on with the provisional order as it originally stood, the mayor making an eloquent speech in favour of the same, pointing out that the death-rate of the town was conspicuously high, and that other towns in which compulsory notification was in force had stamped out, or nearly so, infectious disease. How this will be done in Wigan, provided the authorities get these powers, is difficult to say, for at the present time they have no hospital with anything like adequate accommodation, and it will take at least twelve months before one can be built and equipped, for a site for the same has not been found or finally fixed upon. The last time that Wigan sought these powers the opposition was so strong that the Bill had to be abandoned. If Wigan is to obtain such powers, which no doubt are beneficial for curtailing epidemics of infectious diseases, the town should at once equip a proper hospital for means of isolation, and should also throw the onus of notification on to the householder.

THE HEALTH OF THE CROWN PRINCE.

OWING to an unfavourable change having, we regret to learn, taken place in the laryngeal symptoms of his Imperial Highness the Crown Prince of Germany, Sir Morell Mackenzie has been summoned to San Remo. He left London on Wednesday morning, and would arrive at his destination on Thursday night.

CHRONIC GLANDERS SIMULATING SYPHILIS.

DR. SAKOTSKI, writing in the *Meditsinskoe Obozrênie*, describes the case of a young soldier who suffered from ulceration of the palate, which extended into the nasal cavity, and destroyed the inferior turbinated bones. This was followed by a tumour of the eyebrow, by pains in the knee and ankle, suppuration of the left ear, and a metastatic abscess on the back of the right hand. There was at times some evening pyrexia. The case was looked upon as probably syphilitic for about two years. Then nodules and œdema began to appear on the face, and it was believed that it was glanders. After death, which was due to exhaustion, Dr. Vigandt made a microscopical examination of sections of the nodules, and also examined the ichor of the ulcerated surfaces, finding bacteria resembling those described by Löffler and Schutz, but he was unable to prove them to be the true cause of glanders.

DEATHS OF EMINENT FOREIGN MEDICAL AND SCIENTIFIC MEN.

THE deaths of the following foreign medical and scientific men are announced:—Dr. Max Michael Eulenburg, founder of the well-known Orthopedo-gymnastic Institute in Berlin, at the age of seventy-six.—Professor Arthur Christiani, of the Physiological Institute of Berlin, a great authority on the physiological action of electricity, on the physiology of the nervous system, and on that of the sense of hearing.—Dr. K. Langer, Professor of Anatomy in Vienna.—Dr. Joh. Alexander Chrastina, dean of the Doctoren-Collegium of the Medical Faculty of Vienna.—M. Rambaud, assistant Professor of Clinical Medicine in the Faculty of Lyons.—August Stromeyer, one of the oldest German chemists of eminence, in the eighty-first year of his age.—Dr. Carl Passavant, the African traveller at Honolulu, at the age of thirty-three.—M. le Dr. Giraudet, Professor of Anatomy in Tours.—Dr. A. de Almeida of Oporto.

THE WOMEN'S JUBILEE FUND AND NURSES.

THE public will anxiously await the decision of the Committee appointed by Her Majesty for working out a scheme for improving the condition of nurses labouring among the sick poor. The scheme is being matured by the Duke of Westminster, Sir James Paget, and Sir Rutherford Alcock. Nursing the poor is a branch of work of the very highest importance, and is largely done by ladies, who sometimes of their own limited means subscribe generously to the maintenance of the Associations in connexion with which they work. The vital points to be ensured are that the money shall be so placed as to command the confidence of the public and benefit the sick poor, as well as those who nurse them in their straitened homes under every disadvantage.

FOREIGN UNIVERSITY INTELLIGENCE.

Kazan.—Dr. V. Razumovski, *privat-docent*, has been promoted to the Professorship of Operative Surgery.

Lyons.—The professors of the four Faculties have arranged to issue a quarterly volume of Proceedings. In this way it is hoped that the claim of Lyons to possess a complete and autonomous university may be kept before the public, and that the authorities in Paris, whose regulations are looked upon as rather clogging the wheels of the provincial Faculties, may be induced to concede to some extent the principle of decentralisation. The special point of trouble at present is connected with the "modified Bachelor of Science" examination, which all medical students are compelled to pass.

Marburg.—The Professorship of Surgery which will become vacant at the end of the current winter session is likely to be offered to Professor Braun of Jena.

SIR JOHN PULESTON, M.P., presiding on the 13th inst. at the annual meeting of the Royal Albert Hospital, Devonport, said he regretted the action of Parliament in repealing the compulsory clauses of the Contagious Diseases Acts, and announced his intention at the commencement of the next session to introduce a Bill in Parliament entitled "The Retention in Hospital Bill." It would apply only to women who came to the hospital voluntarily, but would compel them to remain there until they were cured.

AN inquest was held in Marylebone, on the 7th inst., concerning the death of Mr. J. G. French, F.R.C.S., when the jury returned a verdict of "Death from syncope." The deceased, who was eighty-three years of age, was found dead in bed on the 4th inst.

IT is announced that the successful series of *Tableaux Vivants* lately exhibited at the New Club, Covent Garden, will be repeated at 3 P.M., on the 22nd inst., for the benefit of the funds of the Middlesex Hospital.

WE have received a copy of the petition of the Master Wardens and Society of the Art and Mystery of Apothecaries of the City of London, which we hope to be able to reproduce in our next issue.

DR. H. W. G. MACKENZIE, resident assistant surgeon to St. Thomas's Hospital, has been appointed Medical Registrar.

SOME OF THE

INFECTIOUS DISEASES COMMON TO MAN AND THE LOWER ANIMALS.[1]

BY E. KLEIN, M.D., F.R.S.

THE following is a brief abstract of the more interesting portions of this paper:—

Jenner's views as to the relation of human variola and cow-pox are so well known that it is unnecessary for me to enter into them, and likewise Ceely's classical papers in the Transactions of the Provincial Medical and Surgical Society and Dr. Badcock's results have more than once been discussed and commented upon. Ceely, by direct inoculation of human variola into heifers, has succeeded in two instances in producing vesicles identical with those of the natural cow-pox, and in transmitting the lymph from them into generations of human beings as vaccinia; he has thus proved that vaccinia is a modified human variola, having obtained this modification by its passage through the cow. Now it is known that the French Commission under Chauveau arrived at a different conclusion. They were unable to produce such a result as Ceely did by inoculating calves and heifers with human variola; in some instances they assert to have produced a papular eruption at the seat of inoculation; the matter of such papules when inoculated into human beings produced, again, variola. They concluded from these experiments that human variola is transmissible to the bovine species as variola, but does not produce vaccinia. That this conclusion does not necessarily follow from the experiments of the French Commission has been very ably argued by the late Dr. Seaton and others. All that can be said of the work of the French Commission is that their attempts to produce vaccinia by means of human variola were negative. I can fully appreciate these negative results, because some years ago I have myself had opportunity, under the late Dr. Seaton and under the late Mr. Ceely, to make such inoculations on a large scale. Over thirty milch cows and heifers had been inoculated with lymph of human variola; fluid condition and dried on points, taken from cases of confluent small-pox in different stages; clear lymph, purulent lymph, and crusts. Every animal was inoculated in from six to twelve places, each place being made up of a number of simple or crossed incisions about half an inch or more, and a large quantity of lymph was rubbed into each place of inoculation. Many of the animals were thus repeatedly inoculated. But in no instance was there produced a vesicle, or anything comparable to a cow-pock. We concluded from these experiments that to obtain a positive result an unknown additional condition is required, which was absent in our experiments. I am afraid that as long as the present uncertainty as to the exact nature of the virus of vaccinia and variola remains, no clear experimental proof will be obtainable, unless it be that a different method of experimentation with variola lymph is employed than has hitherto been followed. As regards the first—i.e., the nature of the virus—various assertions have been made from time to time, without, however, bringing us much nearer to the exact understanding. F. Cohn has, many years ago, ascertained the presence of micrococcus of the character of streptococcus in the lymph of variola and vaccinia; Sanderson confirmed this; Weigert found micrococci in the lymph of the vesicles and lymphatics of the variola eruption; Pohl Pineas described them also in the tissue of the epidermis of vaccinia. Dr. Paul Guttmann isolated, by cultivation after the modern methods, three different varieties of micrococci from the lymph of vaccinia and variola; so did also Dr. Buist. I show you here a streptococcus which is constantly present in human vaccinia, which corresponds to one of the streptococci isolated by Guttmann, and which he regards as the vaccinia streptococcus. Quite recently it has been, however, maintained that none of the species of micrococci hitherto isolated by the gelatine method can be the virus of vaccinia, but that it probably is some other organism not capable of growing in gelatine. The fact of the matter is, no one has yet succeeded in making a successful inoculation experiment with any of the organisms isolated from either variola or vaccinia. In saying this I am quite aware of the assertions of Dr. Buist, who claims to have succeeded in this; but reading his statements, and comparing them with his experiments, I think you will agree with me that they do not carry a great amount of conviction.

[The subjects of *hydrophobia* and *diphtheria* were then discussed by Dr. Klein, who then proceeded to the consideration of *scarlet fever*. He said that it would, no doubt, be in the recollection of the Society that at the end of 1885 and the beginning of 1886 an extensive outbreak of scarlet fever occurred in Marylebone, which Mr. Wynter Blyth has traced to be due to consumption of milk coming from a particular farm at Hendon. Mr. Power supplemented this by finding that cases of scarlet fever occurring also in other districts of the metropolis were likewise to be referred to the milk of the same farm. With Dr. Cameron, medical officer of health of the Hendon district, Mr. Power was able to exclude all and every accidental contamination of the milk of this farm from human source. Mr. Power had further shown "that only certain sections of the milk supplies within the farm, and eventually certain cows, as having to do with the infectivity of the milk."] The report of Mr. Power is known to you, and I think you will agree with me that in reading it, and following from step to step the clear and precise observations of Mr. Power, we cannot refuse admitting the correctness of his conclusions. It is not

[1] Read at the Epidemiological Society of London, on Dec. 14th.

Digitized by Google

my object or my place to defend Mr. Power's conclusions—he is quite capable of doing so himself; but I will undertake to say this, that to an unbiased reader the methods by which he arrived at those conclusions are unimpeachable, and the proof amounts almost to a mathematical demonstration..... A point that our opponents have brought forward refers to a disease in the cow which, it is alleged, is the same, and has the same origin, as the Hendon disease, but has not produced infection of human beings with scarlatina. Now let me first remind you what the conditions of the Hendon disease were. I will quote the concise summary given by the medical officer of the Local Government Board, in his Report of 1885-86, pp. vi. and vii.: "In the end," says the medical officer, "he (Mr. Power) has demonstrated beyond reasonable doubt the dependence of the milk-scarlatina of December on a diseased condition of certain milch cows at the farm; a condition first introduced there in the previous month by some animals newly arrived from Derbyshire; and he finds strong circumstantial evidence for believing that the later phenomena of this dependence were brought about through the extension of the diseased condition of one set of animals to another set, after the fashion of an infection." This disease in the Hendon cows manifested itself in the following symptoms:[2] ulcerations covered with scabs on the teats and udder, ulceration, scabs, scurfiness, and loss of hair in patches in different parts of the skin; the animals were thin, and exhibited slight cough, but showed no rise of temperature. The viscera of two animals killed showed: slight pleuritis, with recent fibrinous deposits and adhesions; congestion and extravasations of blood in many lobules of the lungs; discoloured softened patches in the liver tissue; ecchymoses and petechiæ in the tissue and in the capsule of the spleen; swelling of, and extravasations of blood in, the lymphatic glands; congestion and glomerulo-nephritis of the cortex of the kidney; in some also interstitial new growth. With the material of the ulcers the disease was reproduced in the skin of calves; from the tissue of the ulcers of the Hendon cow an organism was isolated by cultivation, of which the characters in the depth and on the surface of gelatine, on agar-agar mixture, in broth, milk, and on blood-serum, were minutely studied, and hereby its identification became possible. This streptococcus, when inoculated into calves, produced a visceral and sometimes cutaneous disease, mild in character, and which very much resembled that of the Hendon cows. With this organism, by feeding or inoculation, a disease ending fatally in a large percentage was produced in grey house-mice: from the heart's blood of these the same micrococcus was recovered by cultivation. Professor Axe has presented a report to the Agricultural Department of the Privy Council Office, in which he states that in two different localities cows had been affected with ulceration of the teats and udders, and that the disease had been introduced at the same time into these localities by infected cows coming from the same dealer in Derbyshire, that had supplied those incriminated first cows to the Hendon farm, but in those two localities no scarlet fever had been produced amongst the consumers of the milk. Now let me here say that this dealer in cows in Derbyshire had at first stoutly refused any and every information to Mr. Power; but some months afterwards, when this investigation at the Hendon farm had to a great extent implicated the stock of this Derbyshire dealer, he had altered his mind, and offered all the above information. It would seem, in such a case, that some corroboration of the statements and observations of the Derbyshire cow-dealer should have been forthcoming. I do not question for a moment that Professor Axe had correctly reported what he heard and saw as to the ulceration on the teats and udders in the two herds, and that he had been told and had observed that the disease spread in each herd, and that it was introduced there by cows coming from the dealer in Derbyshire above mentioned. But what I should like to be permitted to question is the reliance that ought to be placed on the information offered by the above Derbyshire dealer—i.e., whether about the same time and from the same stock that he supplied cows to the Hendon farm he also supplied those two other localities. That the disease observed in these two localities is the same as that at the Hendon farm there is no evidence whatever; sores and ulcers on the teats and udders of cows of an infectious character are known in veterinary pathology, and they are known to be of various kinds. In connexion with this I will mention one striking coincidence that refers to this Derbyshire dealer. It will be, no doubt, in your recollection that an extensive outbreak of scarlet fever occurred at and about Wimbledon at the end of the last and the beginning of this year. This epidemic was traced distinctly to milk coming from a particular farm. Now the curious thing about this farm is that it belongs to a dairy farmer of the name of Keevil, who happens to be the brother of our Derbyshire dealer, and who had received some of his cows from this same dealer shortly before the outbreak of scarlet fever in Wimbledon. The way that this Wimbledon milk had received the contagium has not been ascertained by Mr. Power, but the fact that the Wimbledon dairy farmer Keevil had got cows from the Derbyshire dealer Keevil, who had supplied the Hendon farm, is, I think, extremely suggestive. Owing to the kindness of Professor Brown, I have been enabled quite recently to observe a cow which belonged to a herd in which a contagious ulcerative disease of the teats and udders prevailed, which was supposed to be the same as that of the Hendon cows. No cases of scarlet fever have been known in connexion with these cows. The ulcers on the teats were very extensive, superficial, irregular, and covered with brown crusts, the teats themselves much swollen. Taking off the crusts and scraping the superficial part of the ulcers, and then taking material from the deeper part of the ulcer and inoculating gelatine, I succeeded in isolating four different species of micrococci—(*a*) micrococcus citreus; (*b*) micrococcus aurantiacus; (*c*) staphylococcus pyogenes; (*d*) a micrococcus, which in plate cultivation, on the surface and in the depth of gelatine, presented characters resembling the micrococcus scarlatinæ, obtained from the Hendon cows and from human scarlet fever. But it soon became apparent that it is an altogether different species; it grew much more slowly, and its colonies (minute circular dots) are much more transparent than those of the Hendon cow organism; further, while the micrococcus of the Hendon cow and of human scarlet fever grows well in broth, producing after two days at 35° C. a distinct turbidity, and also well on the surface of agar-agar mixture, as isolated whitish dots; the micrococcus in question isolated from the ulcer of Professor Brown's cow does not show any growth on agar-agar mixture, or in broth, even after a five days' sojourn in the incubator at 35° C. The animal in question was killed after about a fortnight, when the ulceration and swelling of the teats were still considerable. The left hind-quarter of the udder was found very tense, and greatly swollen; on incision, a large quantity of thick, grumous pus was found in this portion. The lungs were normal, the spleen was normal, the liver exhibited a few whitish irregular spots, and the kidney presented a few fatty patches on the surface of the cortex; none of the lymphatic glands showed the hæmorrhage into their substance. During life the animal had, all the time while under observation, high temperature, varying between 105° and 104° F.; and no wonder, seeing the extensive suppuration that was going on in the udder. There can, then, be no question that this cow did not show the same disease that was observed in the Hendon cows, nor was the same organism obtained. Two other cows were kindly given me by Professor Brown, and also in these the same condition was present and the same result was obtained by culture and in the post-mortem examination.

The last point of opposition urged is that of the so-called bacillus scarlatinæ of Edinburgh. Dr. Edington has isolated from the epidermis during the stage of desquamation of scarlet fever cases a bacillus which he considered to be the bacillus of scarlatina. He maintained that this bacillus is present in all cases of scarlet fever in the blood before the third day; it then disappears from the blood in order to appear in the skin, whence it is discharged into the epidermis, and here forms spores during the stage of desquamation. In the first place, let me remind you that various species of bacilli and micrococci have been hitherto isolated from the epidermis of the normal skin. In the second place this bacillus of Edington has not been found in all early cases of scarlet fever by a committee of the Medico-Chirurgical Society of Edinburgh, appointed to test Dr. Edington's assertion, only in the blood taken from a prick in the finger of two out of ten cases of scarlet fever on or before the third day. Anyone acquainted with the modern methods of bacteriological inquiries will agree with me when I say that there is no difficulty whatever for anyone who devotes the necessary time to it to isolate by the modern exact

[2] The description given by Dr. Cameron of the Hendon disease is admittedly and to a large extent based on various statements by different persons who in previous years and at different localities maintain to have observed a disease in cows similar to the Hendon disease.

Digitized by Google

methods new species of bacilli or bacteria in any material he chooses to select ..... The point, therefore, in the present state of bacteriological researches is not whether in any morbid material of the body this or that new species is present, but whether in its distribution and its action it bears any definite relation to that morbid process. Now everyone acquainted with these fundamental conditions will understand that one of the first and essential conditions would be that a microbe which is to bear any relation to scarlet fever must be found in the blood or tissues in a definite distribution. Examining the desquamating epidermis and finding a new species of bacteria may mean nothing more than this—viz., that to those several species already known to exist in the epidermis, another species has been added, which, in itself, is no doubt an interesting discovery, as much as, for instance, is a new species of diatome or a new beetle in a locality where no one has seen it before. But this new addition to the list of bacilli in the epidermis may have nothing whatever to do with the scarlet fever. This so-called bacillus of scarlatina is a bacillus which belongs to a well-defined group of species which in former years would have been considered as bacillus subtilis—viz., rods of a certain length and thickness, mobile; they have a tendency to form long chains or leptothrix; they grow rapidly in broth, and form here on the surface a scum, which is already well developed after twenty-four hours; the scum thickens during the next days, and becomes corrugated, the fluid itself remaining clear, but gradually becoming brownish—the more brown the longer time elapses; they liquefy rapidly gelatine, and after some days form also here a scum on the surface; they form in a few days a corrugated scum on the surface of solid agar-agar mixture; they grow rapidly in milk which is curdled, and by which a white precipitate is formed, while the fluid, at first turbid, gradually becomes clear; on its surface there is a thick pellicle. In plate cultivations in gelatine, the bacilli form minute whitish colonies, at first—i.e., during the first day angular, after thirty hours or more gradually liquefying the gelatine, and forming circular colonies of liquefied gelatine with an opaque or slightly granular outline, and a central, whitish spot due to precipitate of masses of bacilli. On potato they grow rapidly, and form a more or less corrugated layer, gradually turning brownish. Now I know of five different species; all notoriously septic bacilli, which show these characters besides the Edinburgh bacillus; they show, nevertheless, slight differences, and may be considered as different species, but as to those general characters just mentioned, there is no doubt they belong to the same group of organisms. To sum up, then, the Edinburgh bacillus, judging by its mode of growth, clearly belongs to a group of species of bacilli which are notoriously septic bacilla. It has been found in a small percentage of cases of scarlet fever in blood taken from a prick of the finger; its spores occur in the epidermis of cases of scarlet fever, amongst other species of bacteria; it has no action when the bacilli or spores are injected subcutaneously, and in a pure state, into animals. You will, I think, agree with me that after such evidence, it would be quite unjustifiable and premature to call this bacillus the bacillus of scarlet fever. This whole question of the etiology of scarlet fever is no doubt an extremely difficult one, and only by combined work on an extensive scale, and by careful and accurate methods, can we hope to get at the truth of the matter; and in these efforts no criticism should be shunned or objected to, but, on the other hand, it must be criticism made in an unprejudiced and scientific spirit.

COMPLIMENTARY BANQUET TO SIR ALFRED GARROD, M.D., F.R.S.

ON Tuesday, Dec. 6th, Sir Alfred Garrod was entertained at a complimentary banquet by the members of the medical profession resident in his native town, Ipswich. The chair was occupied by Dr. Caleb Rose, and the vice-chair by Mr. George Cordy Edwards, almost every practitioner of the town being present. The health of the distinguished guest was given by one of the senior surgeons of the hospital (Dr. Elliston), who referred to the high honour conferred upon Sir Alfred by Her Majesty, in selecting him as one of the few distinguished physicians who had received the prestige of knighthood in her Jubilee year, a distinction which reflected credit upon himself, and redounded to the honour of the town in which he was born and educated, and received his early medical education. The Ipswich school was proud to claim Sir Alfred Garrod as an old boy. After leaving school, he was apprenticed to the late Mr. Charles Hammond, one of the then surgeons of the East Suffolk Hospital. Thence he proceeded to University College, London, graduated at the University of London in 1843, and became successively attached to University College and King's College Hospitals as physician. He was now consulting physician to King's College Hospital, a Fellow of the Royal Society, and had for many years been known as a most successful teacher of materia medica and therapeutics, besides being one of the most actively employed of the physicians of the day. Dr. Elliston referred to the well-known works of their visitor, and particularly to his treatise on Gout and Rheumatic Gout, which, he thought, entitled him to grateful and lasting recognition. Sir Alfred had done for the elucidation of these allied diseases what Jenner had done for continued fever. The toast was most warmly received, and Sir Alfred Garrod, in response, spoke of his pleasing recollections of his early life at Ipswich, and of the pleasure he felt in responding to the invitation to visit them after so many years' absence. He recalled to memory the names of many able physicians and surgeons who were then living and practising, but are all dead, although he was pleased to see several of their descendants present.

BRITISH NURSES' ASSOCIATION.

A REPRESENTATIVE gathering of the matrons of the metropolitan hospitals and infirmaries, and other well-known members of the nursing profession, was held at Mrs. Bedford Fenwick's residence on Saturday last, to discuss the advisability of forming an Association for the mutual help of all women engaged in nursing the sick, and for the advancement generally of their professional usefulness both to medical men and the public. At this meeting it was pointed out that a heterogeneous Association was attempting to legislate for the nursing profession, and had issued regulations for the registration of nurses, which, it was considered, were degrading to them as a body. Furthermore, that there are now about 15,000 nurses in the United Kingdom, isolated individuals, who, with their scanty salaries, can do little to help themselves or each other if incapacitated by illness or age from further work. After some discussion, it was unanimously agreed that a British Nurses' Association should be formed, having for its objects (1) the obtaining of a charter that will enable the Association to examine and register nurses and to confer degrees; (2) the starting and carrying on of a journal of the Association, which shall be exclusively devoted to the interests of nurses; (3) the devising of schemes for annuity pension, and sick funds for nurses; (4) the formation and managing of a convalescent home and holiday house for nurses; (5) the founding and managing of almshouses for superannuated nurses; and (6) the organisation of conferences on questions relating to the nursing profession. Bye-laws were passed, a general council constituted, and an executive committee appointed, on which the following matrons at once consented to act: Mrs. Deeble (Netley Hospital), Miss Hogg (Haslar Hospital), Miss Stewart (St. Bartholomew's Hospital), Miss Jones (Guy's Hospital), Miss Thorold (Middlesex Hospital), Miss Wood (Children's Hospital), Miss Sutcliffe (Women's Hospital), Miss Clarke (Western Fever Hospital), Miss East (National Hospital), Miss Mollett (Chelsea Infirmary), Miss Close (Kensington Infirmary), Miss Beachcroft (Lincoln County Hospital), Miss Rogers (Leicester Infirmary), Miss Gibson (Brownlow Hill Infirmary. Liverpool), and Miss Huxley (Sir Patrick Dun's Hospital, Dublin). Mrs. Bedford Fenwick, lately matron of Bartholomew's Hospital, and five other ladies were also nominated to act with the above. The movement has, we are informed, been warmly welcomed, and is assured already of influential support.

A MEETING of the supporters of the Surgical Aid Society was held on the 7th inst., the Lord Mayor presiding, when satisfactory reports of the progress of the Society were presented.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN twenty-eight of the largest English towns 5542 births and 3746 deaths were registered during the week ending December 10th. The annual rate of mortality in these towns, which had been 23·5 and 22·5 per 1000 in the preceding two weeks, further declined last week to 21·1. During the first ten weeks of the current quarter the death-rate in these towns averaged 20·6 per 1000, and was 0·9 below the mean rate in the corresponding periods of the ten years 1877-86. The lowest rates in these towns last week were 15·6 in Plymouth, 15·9 in Brighton, 16·8 in Huddersfield, and 17·5 in Hull. The rates in the other towns ranged upwards to 29·9 in Blackburn, 30·3 in Portsmouth, 31·5 in Oldham, and 33·2 in Newcastle-upon-Tyne. The deaths referred to the principal zymotic diseases in the twenty-eight towns, which had been 480 and 443 in the preceding two weeks, were last week 448; they included 116 from whooping-cough, 91 from scarlet fever, 77 from "fever" (principally enteric), 73 from measles, 44 from diphtheria, and 20 from small-pox. These zymotic diseases caused the lowest death-rates last week in Cardiff, Halifax, and Plymouth, and the highest rates in Portsmouth, Birmingham, Sheffield, and Derby. The greatest mortality from whooping-cough occurred in Wolverhampton, Portsmouth, and Newcastle-upon-Tyne; from scarlet fever in Blackburn, Huddersfield, and Oldham; from "fever" in Preston, Newcastle-upon-Tyne, Blackburn, and Bolton; and from measles in Nottingham, Birmingham, and Derby. The 47 deaths from diphtheria in the twenty-eight towns included 27 in London, 3 in Brighton, 3 in Manchester, 2 in Portsmouth, and 2 in Sheffield. Small-pox caused 17 deaths in Sheffield, 2 in Bristol, and 1 in Hull, but not one in London or in any of the twenty-four other large provincial towns. The metropolitan hospitals receiving cases of small-pox contained 10 patients on Saturday last, against 16, 13, and 12 on the preceding three Saturdays. The number of scarlet fever cases in the Metropolitan Asylums Board hospitals and in the London Fever Hospital at the end of the week was 2667, against 2764 and 2726 on the previous two Saturdays; the cases admitted also showed a decline from the numbers in recent weeks. The deaths referred to diseases of the respiratory organs in London, which had been 560 and 455 in the preceding two weeks, further declined last week to 408, and were 79 below the corrected average. The causes of 73, or 1·9 per cent., of the 3746 deaths in the twenty-eight towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Portsmouth, Leicester, and in five other smaller towns. The largest proportions of uncertified deaths were recorded in Halifax, Sheffield, and Huddersfield.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had steadily increased in the four preceding weeks from 19·9 to 25·0 per 1000, declined again to 22·7 in the week ending Dec. 10th; this rate exceeded, however, by 1·6 the mean rate during the same week in the twenty-eight large English towns. The rates in the Scotch towns last week ranged from 16·5 and 19·4 in Leith and Perth, to 23·9 in Glasgow, 24·4 in Aberdeen, and 32·5 in Paisley. The 567 deaths in the eight towns last week showed a decline of 59 from the number in the previous week, and included 29 which were referred to whooping-cough, 14 to scarlet fever, 14 to measles, 13 to diarrhœa, 5 to "fever" (typhus, enteric, or simple), 4 to diphtheria, and not one to small-pox; in all, 79 deaths resulted from these principal zymotic diseases, against 78 and 77 in the preceding two weeks. These 79 deaths were equal to an annual rate of 3·2 per 1000, which exceeded by 0·7 the mean rate last week from the same diseases in the twenty-eight English towns. The fatal cases of whooping-cough, which had been 30 and 28 in the preceding two weeks, were last week 29, of which 17 occurred in Glasgow and 6 in Edinburgh. The 14 deaths from scarlet fever showed a further slight increase upon the numbers in recent weeks, and included 6 in Glasgow, 5 in Dundee, and 2 in Perth. The fatal cases of measles, which had been 8, 13, and 12 in the previous three weeks, rose last week to 14, of which 6 occurred in Leith, 5 in Dundee, and 3 in Edinburgh. The 13 deaths attributed to diarrhœa showed an increase upon the low numbers in recent weeks; 7 were returned in Glasgow and 3 in Edinburgh. The 5 deaths referred to "fever" were fewer than in any recent week, and included 2 in Glasgow and 2 in Edinburgh. Three of the 4 fatal cases of diphtheria occurred in Glasgow. The deaths referred to acute diseases of the respiratory organs in the eight towns, which had increased in the preceding four weeks from 107 to 165, declined again last week to 143, and were 1 below the number returned in the corresponding week of last year. The causes of 60, or nearly 11 per cent., of the deaths registered in the eight towns during the week were not certified.

HEALTH OF DUBLIN.

The rate of mortality in Dublin, which had been 34·6, 33·8, and 35·0 per 1000 in the preceding three weeks, further rose to 35·6 in the week ending December 10th. During the first ten weeks of the current quarter the death-rate in the city averaged 31·0 per 1000, the mean rate during the same period being but 19·8 in London and 19·7 in Edinburgh. The 241 deaths in Dublin last week showed a further increase of 4 upon the numbers in recent weeks; they included 15 which resulted from scarlet fever, 6 from measles, 4 from "fever" (typhus, enteric, or simple), 3 from whooping-cough, 3 from diarrhœa, and not one either from small-pox or from diphtheria. Thus the deaths resulting from the principal zymotic diseases, which had been 33 and 31 in the previous two weeks, were again 31 last week; they were equal to an annual rate of 4·6 per 1000, the rate from the same diseases being 2·6 in London and 3·2 in Edinburgh. The fatal cases of scarlet fever, which had been 20, 8, 11, and 13 in the preceding four weeks, were 15 last week. The 6 deaths from measles showed a decline of 2 from the number in each of the previous two weeks. The deaths from the other zymotic diseases scarcely differed from those in the previous week. The deaths of infants showed a slight increase, while those of elderly persons were fewer than in either of the previous two weeks. Five inquest cases and 3 deaths from violence were registered within the city; and 57, or nearly a quarter, of the deaths occurred in public institutions. The causes of 37, or more than 15 per cent., of the deaths in the week were not certified.

"Audi alteram partem."

ALBUMINURIA IN THE APPARENTLY HEALTHY.

To the Editors of THE LANCET.

SIRS,—I have read with considerable interest Dr. Stirling's able paper on the above subject in your issue of the 10th inst.; but should, however, like to make a comment on one point, concerning myself, with regard to it.

Dr. Stirling remarks that he cannot agree with me "that the one cause of this albuminuria is an increased hæmolytic action of the liver." From this I fear that in my paper on the subject, published in THE LANCET of Oct. 23rd, 1886, I did not make it sufficiently plain that I intended this to apply only to that form of functional albuminuria which strongly resembles hæmoglobinuria in its paroxysmal character, and with which, indeed, I believe it is allied. This paroxysmal albuminuria has not always a marked cyclical character, since it may occur indifferently at any period of the day, and sometimes is continuous for days together, though the effect of a meal is generally to be observed by an increase of the amount of albumen in the urine. Its most marked feature is the feeling of malaise, frequently accompanied by sallowness, coming on suddenly in a person apparently previously healthy. The sample of urine next passed contains albumen, and is also characterised by containing more urea and urobilin, and in being of a higher specific gravity than the generality of samples passed by the same individual. The attack may pass off at once and the succeeding samples be free from albumen, but usually there is persistence for some days. In addition to the three cases published in THE LANCET, I have now under observation a member of our profession in whom the malaise, when it occurs, is well marked, and whose urine invariably shows the above-men-

Digitized by Google

tioned characteristics; for in a long series of observations I have noted that the albuminous urines are always of a higher specific gravity and contain more urobilin than any that he sends me when his urine is free from albumen. In his case the beneficial effect of arsenic is well marked, since the albuminuria disappears more rapidly when he takes a mixture of iron and arsenic than with iron alone.

It is, however, to this *paroxysmal* form of functional albuminuria alone that I would refer increased hæmolytic action of the liver as "the one cause." Indeed, in my work on "Diseases of the Kidneys," pp. 535—540, I have enumerated several other conditions which may cause functional albuminuria in persons apparently healthy, and which I have classified under the following heads, as due to (1) derangements of digestion; (2) disturbed innervation; (3) altered conditions of the blood.

With regard to Dr. Stirling's interesting observation respecting the albuminuria of adolescents, and the difficulty of deciding whether or not masturbation has anything to do with it, I may mention that in a case brought to me last summer, subsequent microscopic examinations of the urine has demonstrated the presence of spermatozoa in the albuminous morning urines.

Another interesting point in connexion with functional albuminuria that requires working out is the connexion subsisting between functional albuminuria and micro-organisms. In two cases at least has my attention been drawn to freshly passed albuminous urines containing micro-organisms, which were not to be found in non-albuminous samples passed by the same individual.

I am, Sirs, yours faithfully,

CHARLES HENRY RALFE.

Queen Anne-street, W., Dec. 12th, 1887.

THE TREATMENT OF CANCER.

To the Editors of THE LANCET.

SIRS,—The value or the worthlessness of Chian turpentine in the treatment of cancer is a subject of such vast importance that it is obvious that any testimony brought forward with regard to it should be of undoubted and unbiased accuracy. It is for this reason that, after much hesitation, I feel reluctantly compelled to correct the report of one of the cases published by Professor Clay in THE LANCET of the 19th ult. Of this case (the last of the series) Mr. Clay remarks, "these notes should be highly appreciated, as the case is unique in regard to independent testimony, combined with a thorough and incontestable diagnosis." The report itself states that "this was a case of undoubted epithelioma, as shown microscopically"; and in your editorial article of the 3rd inst. stress is laid on this, as being "a case confirmed by microscopic examination of a growth removed." The case in question was, with the exception of a short interval, under my care from the beginning to the end of the illness, and I now venture to place before your readers a brief but correct account of its nature, and will leave them to form their own judgment as to how far the above conclusions are warranted by the facts.

The patient, a lady at the menopause period of life, was subject to attacks of menorrhagia. During one of these, having imprudently exposed herself to cold, a severe attack of pelvic peritonitis was the result. After the more acute effects had passed away, there remained considerable thickening in and around the walls of the uterus, which was markedly retroflexed; the thickening was especially marked in the cervix, where there was found at one part on the margin of the os a spot of suspicious hardness. The patient was sent to Brighton to convalesce, and on her return much of the general thickening was found to have disappeared, but the indurated spot on the cervix still remained, and in addition a new feature was for the first time observed. Appearing in but not extending beyond the os was a small papillary growth, having its base within the cervix at a point corresponding to the induration. I may state, however, that this was the first occasion on which a speculum was used, so that the growth may have been in existence for a considerable time previously. I expressed my fears as to the cancerous nature of the case to the patient's son, and she was taken by him to see Mr. Thornton. The report made to me was that Mr. Thornton considered the growth to be of the nature of an enlarged granulation; that he had removed it, and cauterised the base. The case now for a time passed out of my hands. Some time later, on making inquiries, I was informed by the lady's son that the growth had been examined microscopically, and that *no cancerous elements had been discovered.* After a considerable interval I was again requested to see the patient, as it was feared the growth had returned. This I found to be the case, and the patient was once more taken to see Mr. Thornton. The report brought to me (in both instances verbally) was to the effect that Mr. Thornton had pronounced the case to be one of cancer, and did not advise any operative interference. I now suggested that, as Chian turpentine was at this time making some stir, there could be no harm in giving it a trial. The patient was accordingly put under this treatment, which was continued for a year with short intervals of rest. During this time the induration disappeared, and the general health became completely re-established, but the growth (which had *not* been removed by Mr. Thornton on the second occasion) remained, and, for aught I know to the contrary, still remains *in statu quo.* Certainly when I last examined the patient, about eighteen months after commencing the turpentine treatment, there was no change observed in it. Whatever the true nature of this growth may be, I feel bound to confess that the result of the treatment was such as to impress me very strongly in favour of Chian turpentine, and I am now watching with great interest its effects on a case in which there can exist no reasonable doubt of the presence of cancer. The result, whether favourable or not, I shall, with your permission, report in due course in the columns of THE LANCET.

I am, Sirs, yours truly,

Leytonstone, Dec. 10th, 1887. J. KING KERR, M.D.

To the Editors of THE LANCET.

SIRS,—The point at issue between Professor Clay and myself is not whether he declared Chian turpentine to be a "specific" or a "cure" for cancer; but that, with very few exceptions, the profession at large have failed to get the results his treatment gave promise of, and I ask of him, in common with others of greater weight, an opportunity of having his diagnoses and results verified. Physician to a large hospital, one would naturally imagine that during the seven years this remedy has been prominently before the profession many opportunities would have occurred to Mr. Clay of proving to his colleagues the wonders he had wrought; and yet in your last issue Mr. Oliver Pemberton states that an appeal addressed to him on the matter failed to get a satisfactory response; whilst in his letter of the 10th inst., he writes in one part that he is "prompted by a manifest desire only to arrive at the truth"; further on he declines to take part in an inquiry on the ground that "it is obvious that the claims of a large private practice, and detachment from hospital work, prevent me from conducting investigations such as those by M. Pasteur with regard to hydrophobia."

These objections might be easily overcome. There are doubtless members of the staff of one or other of the hospitals in Birmingham who would for such an important investigation as the one suggested place a sufficient number of beds at his disposal, where all the conditions he asks for could be obtained without seriously trenching upon his private work.

So far as I am concerned there is no personal feeling in this discussion; but it is the outcome of failure after failure from the exhibition of Chian turpentine in uterine and other examples of cancer, upon the lines laid down by Professor Clay in his papers.

The time is ripe for this investigation, and should Professor Clay refuse the just demand of the profession, then only one verdict on the matter can be given.

I am, Sirs, yours truly,

Nottingham. GEORGE ELDER.

To the Editors of THE LANCET.

SIRS,—In reply to Mr. Pemberton, I still adhere to my statement that "instances in which the disease [cancer] has been cured are familiar to most practitioners," and am surprised that during forty years, in an almost unlimited field for observation, it has never been his lot to see one.

Allow me to refer your readers to the notes of a case of cancer of the breast,[1] reported by Dr. F. A. A. Smith, where

[1] THE LANCET, 1887, vol. II., p. 565.

Digitized by Google

a primary operation was performed in 1868, the diagnosis being verified by microscopic examination of the tumour after its removal, and where secondary growths have occurred in the cicatrix in 1887—i.e., after an immunity of nineteen years. I wish Mr. Pemberton would define the sense in which he employs the term "cure," and state whether he considers in the case now cited that Dr. Smith "cured" his patient of "cancer" in 1868. Will Mr. Pemberton also inform me in what sense "cancer infiltrating the textures immediately around its origin" differs from cancer as defined by myself in your issue of the 3rd inst.;[2] and how he recognises clinically the commencement of the process of "contamination of the adjacent glands"?

From the evidence before us I cannot at present regard certain cases treated after Mr. Clay's method other than instances in which cancer has been cured, and his success has led me to try Chian turpentine numerous times at the Cancer Hospital. Though unable to point to a single instance in which cancer has been yet cured in my own practice by the internal administration of Chian turpentine, either alone or in combination with local applications—and the value of the latter must not be underrated,—my experience has caused me to regard the remedy as valuable. It checks discharge and hæmorrhage, and allays pain. It would also be most unfair were I to neglect to state that the cases in which I have administered Chian turpentine—and beneficially—were all unsuited for operation on account of the extent of the disease. Had the drug therefore been exhibited at an earlier date, the natural course of the disease might have been arrested. I have employed the drug in a case of perineal fistula, where it acted similarly to copaiba and cubebs.

This observation suggests the possibility that if Chian turpentine will operate favourably upon cancer, its allies may be found possessed of similar or more potent properties. Let me add that, for my part, I am determined to continue an unprejudiced trial of Chian turpentine, and to publish the results at a later period. In the meantime, I should be happy to assist others, having the same object in view, in making careful diagnoses of cases in which cancer presumably exists before the exhibition of the remedy.

I am, Sirs, yours faithfully,

CHAS. E. JENNINGS.

Upper Brook-street, Grosvenor-square, W., Dec. 10th, 1887.

ANTIPYRIN IN THE SICKNESS OF PREGNANCY.

To the Editors of THE LANCET.

SIRS,—I have recently had an opportunity of testing the value of antipyrin as a moderator of the reflex excitability of the nervous centres in a case of obstinate vomiting of pregnancy. Mrs. ——, a lady now in the sixth month of her fourth pregnancy, has been suffering from this annoyance for the last ten weeks. All the usual remedies have been tried without any success, and the sickness when I advised antipyrin commenced every day as soon as the patient awoke, about 7 A.M., and continued at intervals until midday. The first morning the medicine was used it was immediately vomited, and the sickness continued as usual. I then advised that a dose (of fifteen grains) should be taken the last thing at night. The following morning the patient felt comfortable, and got up without being sick; but shortly afterwards the nausea was experienced, and although another dose of antipyrin was taken it did not remain upon the stomach, and for the rest of the morning there was the usual sickness. The dose was then doubled, and I recommended that in the morning the medicine should be taken before any attempt was made to move out of bed. This controlled the sickness until 10 A.M., when it again recurred, and lasted a couple of hours. Not thinking it advisable to push the administration of antipyrin, under the special circumstances of the case, beyond two doses of thirty grains each, I advised the patient to remain content with this half-result.—I am, Sirs, yours sincerely,

Paris, Dec. 12th, 1887. OSCAR JENNINGS.

ETIOLOGY OF PNEUMONIA.

To the Editors of THE LANCET.

SIRS,—In reference to an article on pneumonia dealing with the views of Dr. Baker (of the United States) on its causation, it may be mentioned that an investigation into the statistics of chest diseases in the British army would probably fully confirm his statements. The doctrine of chill from external cold had been generally accepted for practice, and on its authority the introduction of the wearing of flannel shirts by the soldiery was strongly recommended and carried into use. The result in the diminution of cases and mortality from chest complaints caused by exposure to weather was surprising, and has continued equally successful. There may be discovered other agencies, chemical and vital, acting along with and influencing pneumonia, and developed by the vital disturbance that then takes place in the lungs; but experience leads to the belief in the atmospheric agency of cold applied directly to the outside of the chest, and that it (presupposed to be an entity) then penetrates by conduction through the walls of the chamber to the pleuræ, and then into the lobules of the lungs lying next to them. All the vessels are at first contracted to their finest calibres, both on the skin and in the lungs, and so remain for hours probably, causing the feeling of chill. Next, on the patient's removal to house or hospital, with a warmer air, reaction sets in, the circulation rushes into the emptied vessels, already weakened, distends them, and produces the stagnation and effusion called inflammation.

I am, Sirs, yours truly,

J. W. BLACK, Surgeon-Major.

Royal United Service Institution, Whitehall, London.

[2] THE LANCET, p. 1142.

POOR-LAW MEDICAL OFFICERS' ASSOCIATION.

To the Editors of THE LANCET.

SIRS,—Will you kindly insert the enclosed resolution, passed at our Council meeting on December 8th?

"Several cases having been brought before the Council in which alleged errors of diagnosis had been publicly reported, and consequently affecting the professional characters of district medical officers and others, the Council trust that more consideration will be shown by medical officers of health and medical superintendents of public institutions in the expression of any adverse opinions."

I am, Sirs, yours truly,

Dec. 14th, 1887. J. WICKHAM BARNES.

NORTHERN COUNTIES NOTES.

(*From our own Correspondent.*)

THE HEALTH OF NEWCASTLE.

THE high rate of mortality prevalent for some time in the city of Newcastle-on-Tyne has been a foremost subject of conversation here amongst all classes. The daily press also has freely ventilated the matter, and indeed the whole machinery of inquiry has been set a-going down to "interviewing," and all sorts and conditions of practitioners have been pressed to give "their views." In the few remarks here set forth I may say I have not been "interviewed," that my experience of Newcastle extends over twenty-seven years of practice, and that I have freely conversed with men in the profession and others who take an interest in sanitary matters. The principal factors in producing the late high figures in the death-rate are: the geographical position of Newcastle, standing as it does in the narrowest part of England; the late meteorological conditions, mostly characterised by change — not, indeed, intense cold, but cold, with damp, hoar frosts, succeeded by a rising thermometer and westerly or south-westerly wind, veering often to the north and north-east; and, again, fogs—frosts not usually so common here at this season. Add these conditions to a clay soil, on which this city is built, and we have some of the strongest causes for general ill-health in the community. Unlike other cities, the best or more fashionable quarters are not in the west, but in the north and east end. The west end of the city is built on a good slope, and in most parts on high ground, and has rather a better foundation as regards the character of the clay. In some of the north districts the clay extends down fully nine feet, so that in damp weather there must be a greater retention of moisture. The School Board regulations have been blamed for much of the illness. I do not agree with this, for it will always be to the interest of the School Board and its officers to keep up a good standard of health, as securing a good general attendance; but boards are not very sensitive bodies, and I may leave the

Digitized by Google

defence to its able secretary. I believe that what may be called the "bureaucratic" management of the city is not without its faults; disease is often concealed for fear of notification and inspection, with removal of patients and beds. I believe too little attention is paid to cleanliness by the people since these new sanitary arrangements came into vogue, and all or too much is left to the town or landlord to do. The middle and the working classes of Newcastle have a partiality for new streets and new houses, and they will remove in droves to damp, even wet, unfinished houses and streets for no other apparent reason than that they are new, and for this they will leave well-drained streets and well-dried houses. I must, in closing, refer to the habits of a large number of the working classes. Let anyone stand near any one of our numerous "long bars"—which are such a curse to this city- just before they close, and see the stream of heated, excited, and poorly clad men, women, and children rushing from the vitiated and hot atmosphere into the cold air on their way to their wretched homes, and he will wonder no longer that the death-rate is high in Newcastle. Children, too, are both badly fed and clothed, which cannot fail to produce a train of disease. In our markets on any Saturday night infants in arms and older children can be seen partaking with their parents of raw tripe, black puddings, and stale fruit, to be washed down on their way home at the "long bars."

Newcastle-on-Tyne, Dec. 12th.

EDINBURGH.

(From our own Correspondent.)

THE MEDICO-CHIRURGICAL SOCIETY.

AT the last meeting of the Society, held a week ago, two interesting cases of myxœdema were exhibited by Professor Grainger Stewart and Dr. John Thomson. Mr. Annandale demonstrated by means of an admirable cast of the face a new method of restoring the nasal bones to their proper position in cases of profoundly depressed fracture. A transfixing metal wire draws forward the bones with the nasal processes of the superior maxillæ, taking its leverage from a sheet of lead-foil which covers the nose, and at the same time moulds the soft parts and retains them in their natural formation till healing is completed. An extensive paper was presented by Dr. Symington on those physiological variations in the position of the liver which depend upon the alteration in the size of the stomach consequent upon its varying degrees of distension. This paper was richly illustrated by casts, models, and drawings of frozen sections, exhibiting the liver *in situ* in the various postures normally assumed by it, and disposing of certain erroneous impressions regarding its position in the body that have crept into some of the text-books. The paper was received very favourably by the Society, several of the clinical teachers present referring to the extreme importance of the anatomical data referred to as a basis for physical diagnosis. Dr. Skene Keith demonstrated the apparatus employed in the treatment of uterine fibroids according to the method of M. Apostoli, and read a paper dealing with the matter systematically, with copious clinical notes appended, narrating his own and Dr. Thomas Keith's success in following the method. In the discussion that followed, the palm certainly fell to Dr. John Duncan, who, after a passing reference to his own work in the application of electricity to surgical cases, considered carefully the wide question of the action of electric currents as applied to the living tissues. In his opinion a clear distinction must be drawn between the electrolytic and corrosive effects specially valuable in surgical cases, and the neurotic and alterative manifestations produced by the current as applied to uterine neoplasms. Success in applications of both sorts must depend on a recognition of the wide difference of the results desired in the two categories of cases; for whereas in the former, which must be called surgical electricity, certain clearly defined physico-chemical results are aimed at; in the latter, which is strictly a department of medical electricity, the result desired is of a subtle, and as yet undefined, nutritive nature; in the former the current must be strong, concentrated, and local in its field of activity; in the latter more disseminated as regards the whole growth attacked, and not of such strength as to produce electrolytic effects.

THE UNIVERSITY COURT.

The University Court have adopted a proposal aimed at extending the benefits of University teaching to a wider circle than those whose intention it is to enter one of the learned professions. By enacting that a matriculation fee of five shillings shall qualify would-be lay students to enter the precincts of the University, and to enrol themselves in certain of the classes, they have opened a channel of useful activity to many who have been hitherto entirely debarred from the higher paths of education; and at the same time, while still guarding important professional courses from an inundation of "the profane," there can be no doubt that they are enhancing the value and vitality of some of the less crowded courses of lectures by placing them within the reach of many who will gladly avail themselves of so prized an opportunity of self-improvement.

THE ROYAL SOCIETY.

The Royal Society is evincing a stronger desire to develop the medical side of its activities than has been the case for some time. At one stage in its career it was greatly famed for the excellent medical and botanical papers contributed by its Fellows; and it is an evidence of a wish for a return of the halcyon days of those particular branches which relate to medicine that has prompted the unanimous election to seats on the Council of two such energetic representatives of our profession as Drs. Batty Tuke and Sims Woodhead. Their appointment is well timed, since they may well add valuable matter to the Transactions and Proceedings by making them the organs for the publication of work from the new College of Physicians' laboratories over which they preside—the one as curator, the other as superintendent.

Edinburgh, Dec. 13th, 1887.

DUBLIN.

(From our own Correspondent.)

THE ACTION OF THE COLLEGE OF PHYSICIANS AGAINST THE APOTHECARIES' CONJOINT SCHEME.

TO-DAY (Tuesday), before the Vice-Chancellor, application was made to fix the mode of trial of an action by the President and Fellows of the College of Physicians in Ireland against the Governor and Company of the Apothecaries' Hall in Ireland. The College of Physicians wish to have it declared that the defendants are not entitled to hold a qualifying examination under the Medical Act, 1886, or to grant a diploma in respect of medicine within the meaning of the Act, or to hold a qualifying examination in connexion with the Royal College of Surgeons in Ireland. Further, that the Registrar of the Irish Branch Council shall not register any diploma granted jointly by the Apothecaries' Hall and the Royal College of Surgeons. Counsel having appeared for the various parties interested in the matter, the Vice-Chancellor fixed the hearing to take place before him on affidavit. This action for an injunction by the College of Physicians is almost universally condemned by the profession, but as the trial cannot much longer be delayed any detailed comment on the proceedings may be left to a future occasion.

SCIENTIFIC ASSOCIATION, R.C.S.I.

The opening meeting of the second session of this Association, which has been formed in the interests of the students attending the medical school of the College and other medical schools in Dublin, took place last week. The President for the ensuing year (Professor Stoker) delivered an interesting address, which was principally directed to the dangers and inutility in many cases connected with the use of O'Beirne's long injection tube.

ALLEGED TREATMENT FOR HYDROPHOBIA.

The McGauran treatment of this dread disease has of late attracted attention by the persevering way in which it has been brought forward by some credulous people in the north of Ireland as absolutely infallible. It is remarkable that not a single medical practitioner living in the district in which Mr. McGauran resides has the slightest faith in the alleged cure. Surely, if there is any truth whatsoever in the alleged cures, the particulars of at least one well-authenticated cure should be forthcoming. But no; up to the present there has not been one, and the offer of £50 by

Digitized by Google

Dr. Thompson, of Omagh, has failed to obtain such. On the other hand, there are very many undisputed cases of persons bitten by rabid animals having died after treatment by the McGauran method. Until a well-authenticated case of recovery by this method is recorded, a discreet silence on the part of its advocates would be advisable.

BRITISH DENTAL ASSOCIATION.

The first meeting of the Irish branch of the British Dental Association was held last week in the Royal College of Surgeons. The President (Mr. D. Corbett), in his address, said that the labour and duties they had undertaken as members of the British Dental Association were by no means light and insignificant; therefore they must individually, and conjointly with the parent Association, exercise all their influence to compel outside members of the profession to adopt that reform which a conscientious acknowledgment of what the public expected from the educated and honest practitioner of the day should beget. He saw around him young practitioners, and to them he would more particularly address his concluding observations. When urging them forward in the pursuit of knowledge, in the language of a well-known author, he would say "Seek greedily that knowledge which would comfort them, adorn them, and never quit them, which would open to them the kingdom of thought and all the boundless regions of conception, as an asylum against cruelty, the injustice, and the pain that might be their lot in the outer world; that which would make their motives habitually great and honourable, and light up in an instant a thousand noble disdains at the very thought of meanness and of fraud."

THE DERRY MAYORALTY.

At a meeting of the Derry Corporation held last week, Sir William Miller, M.B., surgeon to the County Derry Infirmary, was unanimously elected Mayor for 1888. Sir William Miller, it may be added, has declined to receive any emolument during his year of office.

CASE OF ALLEGED POISONING BY A MEDICAL MAN.

The Cork Grand Jury last week found a true Bill against Dr. Philip Cross, who is charged with having poisoned his wife last June. The trial is proceeding.

The annual ball in aid of the funds of the Dublin Orthopædic Hospital will, it is announced, take place in the New Leinster Hall on the 11th of January next.

Dublin, Dec. 13th.

BELFAST.

(From our own Correspondent.)

THE QUEEN VICTORIA CONVALESCENT HOME.

OF the many schemes that in Belfast were brought before the public to celebrate Her Majesty's Jubilee, none have succeeded so well as that put forward by the Ladies' Committee of the Hospital for Sick Children—to provide a Convalescent Home in connexion with the hospital. The sum aimed at was £3200, and already there is £2500 promised and subscribed. Last week a most successful amateur concert was given, and a sum of over £70 was raised by it for the Convalescent Home. It is very strange that, although this hospital contains forty-five beds, and has an immense extern department, and although students have attended the cliniques given by the physicians and surgeons every year since 1875, the Senate of the Royal University do not see the fairness and necessity of recognising this hospital as a teaching institution in connexion with the Royal University. The number of students who are attending the hospital this year is as large as that of last session.

THE BELFAST MEDICAL STUDENTS' ASSOCIATION.

At a largely attended meeting of the members of the Medical Students' Association, held on Dec. 6th, the following resolutions were passed unanimously:—"1. Whereas the principle adopted by the Royal University of altering their regulations and curriculum, and of making these alterations affect students already matriculated, has been a source of much confusion and injustice in the past, and still continues so, it is resolved that we, the Belfast Medical Students' Association, respectfully protest against this principle as subversive of confidence in the University, and manifestly a breach of confidence on the part of that body. 2. That the members of the Belfast Medical Students' Association respectfully desire to call the attention of the Senate of the Royal University to the fact that since the institution of the third examination there is not a single Belfast man on the list of examiners for the degree examination in medicine. In making this representation they do not wish in any way to reflect on the fairness of the examination, but only to claim the privilege of having one or more of their teachers on the Examining Board." After these resolutions had been passed, a discussion took place on the Best Text-books for Students, which was introduced by Dr. Byers, and on the Importance of Case-taking, which was opened by Dr. Calwell. This Association, under the presidency of Dr. J. A. Lindsay, is, during the present session, in a very healthy and vigorous condition, and is a pleasant bond of union between the students.

THE BELFAST DISTRICT LUNATIC ASYLUM.

The question of the proposed enlargement of this institution came up for discussion at a meeting of the governors on Dec. 12th. Mr. Nugent (inspector) gave his opinion in favour of going into the country for a new site, and building a new asylum altogether in preference to the project of adapting a workhouse, should such a building become available for the purpose. This new building would be a sort of annexe to the present asylum. Mr. Nugent thought it would be more satisfactory and more economical to erect a new building, as workhouses were unsuitable for such purposes, and to render them available the expense of the necessary alterations would be very considerable. Finally, after a long discussion, it was decided to postpone the whole question for three months, and in the meantime a deputation is to wait upon Mr. Balfour, the Chief Secretary for Ireland, for the purpose of inquiring what are the intentions of the Government in reference to the proposed measure for the amalgamation of Irish Poor Law Unions. When the report of this deputation is received the question will again come up for discussion, and probably for final settlement.

Belfast, Dec. 13th.

PARIS.

(From our Paris Correspondent.)

MICROBES AND EXPIRED AIR.

WITH reference to the note on confined air and the development of phthisis by Professor Brown-Séquard, which was published in my letter of last week, I may here give the summary of a communication read by Professor Bouchard at the following meeting of the Academy of Sciences on behalf of MM. T. Straus and W. Dubreuille, tending to prove the absence of microbes in expired air. Lister was the first who made the observation that the air introduced into the pleural cavity after a simple fracture of the ribs (without any exterior wound) produced effects very different from, and infinitely less grave than, those resulting from a pneumothorax consecutive to a penetrating wound of the chest. This fact, he added, was to him a mystery, until—thanks to the germ theory—he understood that it was natural that the air was filtered by the bronchi, one of the offices of which is to arrest the particles of dust inhaled, and to prevent them entering into the pulmonary vesicles. This explanation was confirmed experimentally by Tyndall, who showed that the expired air is "optically pure." The researches of MM. Straus and Dubreuille by the bacteriological methods completely confirmed the experiments of Tyndall. They tended to demonstrate that the air expired, even though optically pure, is almost completely deprived of microbes. The lungs therefore really play, for the micro-organisms, the *rôle* of a filter—a function which Lister attributed to them. Divers experimenters have endeavoured to find in the expired air pathogenic microbes, but always without result. Professor Grancher had performed a great number of experiments on the expired air of phthisical patients, but he had never been able to discover the presence of Koch's bacillus or spores. MM. Charrin and Karth had prosecuted analogous researches, but with negative results. From these facts the authors conclude that when human beings or animals are collected in a confined space, their respiration, far from contaminating the air, tends to purify it—that is,

Digitized by Google

as far as microbes are concerned. This is what might be expected, as the air, on leaving the lungs, contains less of microbes than at its entrance. This fact does not in any way militate against that which was long ago established by MM. Pasteur, Lemaire, Miquel, &c.,—that is, that the microbes are very abundant in the air of crowded rooms such as hospital wards, barracks, &c. The act of respiration has nothing to do with this phenomenon; it is not by the air which they expire—that is, by their breath—that people crowded together charge the surrounding air with microbes; it is by their clothes, by the dust caused by their movements, by their expectoration dried on the floor and blown about in the form of powder, by which the dissemination of the microbes in the air is effected. The respiration of human beings within a closed space contributes its contingent of noxious gases, but it tends to purify the air of the microbes which it contains.

TINEA DECALVANS ("PELADE").

A discussion took place at the Academy of Medicine last week on the contagiousness or non-contagiousness of tinea decalvans ("Pelade"), but without much satisfactory result on either side. Dr. Ollivier has for the third time brought the subject to the notice of the Academy. Considering that this malady is not contagious, the author protested vehemently against the exclusion in schools of the pupils who are affected by it. Dr. Ollivier believes that tinea decalvans is caused by a sudden nervous perturbation, an unexpected emotion, or by very great sorrow. He would therefore recommend that the quarantine to which such pupils are subjected should be removed, and that they should be allowed to prosecute their studies in common with the others. Dr. Hardy, the well-known dermatologist, declared that he entertained an opinion diametrically opposed to that of Dr. Ollivier; Professor Cornil shares Dr. Ollivier's opinion, and stated that what tends to prove the non-transmissibility of tinea decalvans is that one does not find in this affection either cryptogams or micro-organisms which could produce it.

Paris, Dec. 13th.

VIENNA.

(From our own Correspondent.)

THE CHEMICAL CHANGES OF THE BLOOD IN TUBERCULOSIS.

A YEAR ago Dr. Ernst Freund, a pupil of Professor Ernst Ludwig, published the results of his chemical researches on tuberculosis in the *Wiener Medicinische Jahrbücher*, 1886. He stated that he had been able to prepare from the blood, as well as from the tuberculous growths of the organs of twenty-five tuberculous cases examined, an organic body belonging to the group of carbohydrates, exhibiting all the reactions peculiar to cellulose—viz, it was insoluble in the ordinary indifferent solvents, but readily soluble in a solution of cupric hydroxide in ammonia; it was resistant to the action of Schulze's mixture of nitric acid and chlorate of potassium; when dissolved in concentrated sulphuric acid, it was converted into sugar by boiling with diluted sulphuric acid, and when treated with nitric acid, ether, and alcohol, a collodion-like body was obtained; it assumed a blue colour when treated with iodine in presence of concentrated sulphuric acid or of a concentrated solution of chloride of zinc, and a blue colour by adding α-naphthol to its solution in concentrated sulphuric acid. For the sake of control the blood and the normal or pathological organs of thirty other cases were examined, but no trace of cellulose could be found in them. Freund's statements on the occurrence of cellulose in tuberculosis have been confirmed, as I am now informed, by recent researches carried out by Dr. Kabrhel in the laboratory of Professor Horbaszewski of Prague. In continuing his researches on the chemical basis of tubercular disposition, Dr. Freund made examinations of ashes of the blood, and found that there is a considerable increase of the potassium salts in the blood of tuberculous persons, while the sodium salts and phosphoric acid are reduced in quantity. The ash of normal blood contains, according to the researches of Jarisch, 25·31 to 28·62 per cent. of potash, 23·7 to 28·13 per cent. of soda, and 8·0 to 8·96 per cent. of anhydride of phosphoric acid; the ash of the blood of tuberculous persons was found by Freund to contain 29·84 to 37·57 per cent. (miliary tuberculosis) of potash, 12·85 to 18·26 per cent. of soda, and 4·3 to 6·79 per cent. of anhydride of phosphoric acid. The urine in these cases, however, showed no increase of potash. On these results Dr. Freund based a series of therapeutical experiments, which are being carried out in the wards of Dr. Langer. The leading idea of these experiments is to withdraw carbonate of potash from the body and to introduce sodium salts. For this purpose, large doses of phosphoric acid and phosphate of potash, soda, and lime, followed by carbonate and bicarbonate of soda and chloride of sodium, are used. Dr. Freund maintains that some of the cases treated in this way improved, especially those affected with chronic tuberculosis.

THE SERVICES.

Surgeon J. J. Lamprey has succeeded Surgeon-Major P. Connolly as Senior Medical Officer in the West Africa Settlements.

INDIA OFFICE.—The Queen has approved of the following promotions, amongst others, made by the Governments in India:—Brigade Surgeon John Charles Morice, of the Bengal Medical Establishment (dated Oct. 24th, 1887), and Brigade Surgeon William Edward Cates, of the Bombay Medical Establishment (dated Sept. 15th, 1887), to be Deputy Surgeons-General. Surgeon-Major Isidore Bernadotte Lyon, of the Bombay Medical Establishment, to be Brigade Surgeon (dated Sept. 15th, 1887). Surgeons Patrick Alexander Weir, Peter Johnston Freyer, M.D., Percy de Haga Haig, John Lewtas, and John O'Neill, M.D., of the Bengal Medical Establishment; Surgeon John Wilkins Clarkson and Surgeon Joseph Parker, M.D., of the Bombay Medical Establishment, to be Surgeons-Major, all dated Sept. 30th, 1887.

ADMIRALTY.—A good service pension of £100 a year, for medical officers of the Royal Navy, is placed at the disposal of the First Lord by the recent death of Sir W. R. E. Smart.

RIFLE VOLUNTEERS.—4th (Eton College) Volunteer Battalion, the Oxfordshire Light Infantry: Edward Stacy Norris, M.B., to be Acting Surgeon (dated Dec. 10th, 1887).—1st Midlothian (Leith): Surgeon and Honorary Surgeon-Major J. Henderson, M.D., resigns his commission; also is permitted to retain his rank, and to continue to wear the uniform of the corps on his retirement (dated Dec. 10th, 1887).

Obituary.

SIR WILLIAM R. E. SMART, M.D., K.C.B., K.L.H.,

HONORARY PHYSICIAN TO THE QUEEN.

IN the recent death of Sir William Smart the Naval Medical Service and the profession have to deplore the loss of an eminent member, who was a bright illustration of what may be achieved by well-directed ability, persevering industry, and the capacity of seizing, as they occur, opportunities of distinction. Early in life, under the apprenticeship system then customary, and to which he always referred with respect and gratitude, he began his medical studies with a leading practitioner of his native town, Devonport, continuing them in London at St. Bartholomew's Hospital. He was always, and remained to the close of his life, a diligent student, taking the deepest interest in his profession and in all that concerned its welfare. He qualified in 1839, and after a brief experience of private practice joined the Royal Navy in 1841, and served for nine years as assistant surgeon in the *Cruiser* in China, in the *Sapphe* at the Cape of Good Hope and Mozambique, and in the *Trafalgar*, *Hibernia*, and *Queen* on the Channel, Lisbon, and Mediterranean stations. Hitherto Mr. Smart's service had been uneventful, but in 1850, while in the *Queen* flag-ship at Malta, a formidable epidemic of cholera broke out, in combating which his energies had full scope, and his work was so highly appreciated as to lead to his promotion to the rank of Surgeon, his first appointment being to the *Spitfire*. In 1853 he found time to take his Doctor's degree at Aberdeen, and was soon after appointed to H.M.S. *Diamond*, Captain W. Peel (the son of the great Prime Minister). When the Russian war began, and the siege of Sebastopol was determined on, Captain Peel landed with the Naval Brigade, and the ship was converted into

Digitized by Google

porarily into a hospital until huts could be erected on shore for the reception of the sick and wounded of the brigade, who were placed in charge of Dr. Smart. This was the turning point of his career. The admirable efficiency of his arrangements, and the zeal, energy, and humanity he invariably displayed in the duties of the hospital, whither all the worst cases were sent from the front, were soon recognised by the eminent naval officers in command, and on their recommendation he obtained from Lord Raglan the rank and privileges of a first-class Staff Army Surgeon. He also received the Blane Gold Medal for his journal, the war medals, and the decoration of the Legion of Honour. As a further reward of his Crimean service, he was appointed Staff-Surgeon and Storekeeper of the Hospital ship at Hong-Kong. There he had charge of those wounded in the Canton River operations in 1858, and received the thanks of the Admiral, Sir Michael Seymour, and promotion to the rank of Deputy Inspector-General. He now went to Bermuda, and in charge of that hospital and afterwards at Greenwich the next ten years were spent. In 1869 he was advanced to be Inspector-General, and as such held command of Haslar Hospital from 1873 till his retirement in 1877. He was made a C.B. in 1867, and ten years later a K.C.B., having been previously appointed Honorary (Naval) Physician to the Queen. Only a few months ago a good service pension was conferred on him.

This accumulation of honours was fully merited by Sir William Smart for his well-proved administrative ability and his zealous discharge of duty during thirty years' active service. But he was more than a meritorious and successful naval surgeon. He never ceased to keep touch of the profession he loved so well, and of which, except in regard to practice, he continued to be an active member till the end. He joined the College of Physicians in 1860, was a conspicuous member of the British Medical Association, and some time president of its Southern branch, and took a leading part in the Epidemiological Society, as being most congenial to his tastes and former professional work. He became its president in 1874-75, and contributed both before and since several excellent and elaborate papers on the diseases of the climates in which he had served and the epidemics he had encountered. But other fields of literature were also dear to him. His was a familiar figure at the Record Office, the British Museum, and other great libraries of the metropolis, seeking material for his writings and lectures on antiquarian, geographical, and other subjects, in which he employed his learned leisure.

Here, too, mention should be made of the time and earnest anxious labour Sir W. Smart devoted to what was long a burning question of naval administration—viz., the position and emoluments of medical officers. With the late Dr. F. J. Brown of Rochester and other coadjutors, few of whom survive, he adduced evidence and arguments so cogent as in time to overcome the prejudices of the executive and effect the progressive but well-marked improvement that has taken place in the last forty years. For the great share he had in this movement his name deserves to be held in veneration and grateful regard by two generations of his brother officers. His long experience in every sort of vessel in a subordinate capacity had given Sir William an intimate knowledge of the wants and wishes of his younger brethren. "He who wears the shoe can alone tell where it pinches," and one of the happiest consolations of his declining years was the consciousness of having been instrumental in greatly ameliorating their position.

Sir William Smart's nature was eminently sympathetic. Wherever among his relatives and friends there was illness or suffering, he was to be found rendering succour and comfort regardless of his own convenience or repose. In every domestic relation he was exemplary, the most affectionate of kinsmen, and the fastest of friends. He was seen at his best in his family circle and amid his old naval comrades, who could appreciate his genial humour and rich store of anecdote. His great activity of mind and body seemed to betoken longevity. But some time ago chronic, though painless, disease began to enfeeble and emaciate him. He was only five days confined to his house at Harlesden when symptoms of pulmonary and cerebral oppression were manifested, and he died there on Dec. 2nd, having three weeks before completed his seventieth year. On the 6th he was buried in Kingsbury Neasdon churchyard, not far from Willesden. His honoured name will be long remembered with respect, gratitude, and affection.

We have been informed by his son[1] of an interesting incident in the life of Sir William Smart. In the course of duty he had never been under fire, although from indulging his curiosity as a spectator of the siege operations at Sebastopol he had run some risk. But it so happened that in China he was on one occasion accidentally wounded by a pistol bullet. It entered above the wrist, ran up the arm, and lodged between the radius and ulna just below the elbow. He said he could sometimes feel this ball get in between the bones when bending the joint, and cause sudden stoppage of the movement of flexion. With characteristic resolution, Sir William kept this a secret throughout his life, even from his family, because he feared that if known it might injure his prospects of employment as a hospital surgeon. Shortly before his death he expressed a wish that some mention should be made of this wound, the scar of which was visible, in order to show that though a man may have a bullet encysted in his right forearm, he may still be a good operator.

Medical News.

UNIVERSITY OF LONDON.—The following candidates have passed the recent M.B. Examination for Honours:—

MEDICINE.

FIRST CLASS.

Flemming, Percy (Scholarship and Gold Medal), Univ. Coll.
Tubby, Alfred Herbert (Gold Medal), Guy's Hospital.
Eq. Braddon, William Leonard, Guy's Hospital.
Eq. Thane, Edgar Herbert, University College.
Eq. Jecks, Cyril William, University College.
Eq. Smith, Hugh, London Hospital.
Brown, Herbert Henry, University College.

SECOND CLASS.

Moynihan, Berkeley Geo. Andrew, Yorkshire College.
Lys, Henry Grabham, London Hospital.
Eq. Deanesly, Edward, B.Sc., University College.
Eq. Thompson, J. Edwin, Owens Coll. and Manchester Roy. Infirm.
Eq. Featherstone, W. Baritrop, Queen's College, Birmingham.
Eq. Finley, Fredk. Gault, McGill Univ., London Hosp., and Vienna.
Eq. Rennie, George Edward, B.A. Sydney, University College.
Eq. Stedman, Frederic Osmund, Charing-cross Hospital.

THIRD CLASS.

Eq. Fisher, Theodore, Guy's Hospital.
Eq. Solly, Ernest, St. Thomas's Hospital.
Eq. Kelsall, Henry Truman, London Hospital.
Eq. Risdon, William Newt, Guy's Hospital.
Eq. Wheaton, Samuel Walton, St. Thomas's Hospital.
Eq. Brook, W. Henry Breffit, St. Bartholomew's Hospital.
Eq. Wynter, Walter Essex, Middlesex and St. Barthol. Hospitals.
Wheatley, James, King's College.
Eq. Caldecott, Charles, Guy's Hospital.
Eq. Godfrey, A. E., Northamp. Gen. Infirm. and St. Thomas's Hosp.
Eq. Luff, Arthur Pearson, B.Sc., St. Mary's Hospital.
Mumford, A. Alex., Owens Coll. and Manchester Royal Infirm.
Eq. Jordan, Walter Ross, Birmingham Medical School.
Eq. Taylor, Frederick Howard, London Hospital.

OBSTETRIC MEDICINE.

FIRST CLASS.

Thane, Edgar H. (Scholarship and Gold Medal), Univ. Coll.
Jecks, Cyril William (Gold Medal), University College.
Braddon, William Leonard, Guy's Hospital.

SECOND CLASS.

Thompson, J. Edwin, Owens Coll. and Manchester Roy. Infirm.
Flemming, Percy, University College.

THIRD CLASS.

Brown, Herbert Henry, University College.
Wynter, W. Essex, Middlesex and St. Bartholomew's Hospitals.

FORENSIC MEDICINE.

FIRST CLASS.

Braddon, W. Leonard (Scholarship and Gold Medal), Guy's Hosp.
Brook, W. H. Breffit (Gold Medal), St. Bartholomew's Hospital.
Thompson, J. Edwin, Owens Coll. and Manchester Roy. Infirm.
Deanesly, Edward, University College.
Eq. Featherstone, W. Baritrop, Queen's College, Birmingham.
Eq. Fisher, Theodore, Guy's Hospital.

SECOND CLASS.

Wheaton, Samuel Walton, St. Thomas's Hospital.
Luff, Arthur Pearson, St. Mary's Hospital.
Nevins, J. B., Liverpool School of Medicine and Guy's Hospital.
Tubby, Alfred Herbert, Guy's Hospital.

THIRD CLASS.

Tunstall, John Ogle, University College.
Eq. Brown, Herbert Henry, University College.
Eq. Caldecott, Charles, Guy's Hospital.
Eq. Jecks, Cyril William, University College.
Taylor, Fredk. Howard, London Hospital.
Colman, W. Stacy, University of Edin. and Univ. College.

[1] W. Herbert Smart, M.B. Camb., now House-Surgeon of the Hants County Hospital, Winchester.

The following candidates have passed the recent M.S. Examination:—

Burghard, Frédéric François, Guy's Hospital.
Price, Alfred Edward, M.D., Guy's Hospital.
Spencer, Walter George, St. Bartholomew's Hospital.
Targett, James Henry, Guy's Hospital.

The following candidates have passed the recent B.S. Examination:—

FIRST DIVISION.

Carless, Albert, King's College.
Clarke, William Frederick, Guy's Hospital.
Flemming, Percy, University College.
Risdon, William Newt, Guy's Hospital.
Roughton, Edmund Wilkinson, M.D., St. Barthol. Hospital.
Routh, Charles Frederic, Guy's Hospital.
Tubby, Alfred Herbert, Guy's Hospital.
Vincent, Herbert Edmund, Guy's Hospital.
Wheatley, James, King's College.
Wynter, Walter Essex, St. Barthol. and Middlesex Hosps.

SECOND DIVISION.

Braddon, William Leonard, Guy's Hospital.
Brook, William Henry Breffit, St. Bartholomew's Hospital.
Brown, Herbert Henry, University College.
Caldecott, Charles, Guy's Hospital.
Gee, Frederick William, University College.
Heatherley, Francis, Guy's Hospital.
Holder, Sydney Ernest, University College.
Jones, Samuel Cromwell, University College.
Kellsall, Henry Truman, London Hospital.
Prall, Samuel Esmond, Guy's Hospital.
Stedman, Frederick Osmund, Charing-cross Hospital.
Sunder, Charles Edward, University College.
Taylor, Frederick Howard, London Hospital.
Wells, George Lee, St. Bartholomew's Hospital.

UNIVERSITY OF DURHAM.—The following candidates satisfied the examiners at the recent Examinations for degrees in Medicine and Surgery, at the College of Medicine, Newcastle-upon-Tyne:—

DOCTOR IN MEDICINE FOR PRACTITIONERS OF FIFTEEN YEARS' STANDING.

Crawford, James, L.K.Q.C.P.I., L.R.C.S.I.
Deane, Robert Edmund, L.R.C.P. Ed., L.S.A.
Jones, David Edgar, L.R.C.P. Ed., F.R.C.S. Ed.
Steele, Russell, L.R.C.P. Ed., M.R.C.S.

DOCTOR IN MEDICINE (ESSAY).

Barker, John, M.B., M.R.C.S., L.S.A.
Cripps, Charles Couper, M.B., M.S., M.R.C.S.
Davidson, Charles Robert, M.B., M.R.C.S.
Harper, Alexander, M.B., M.R.C.S.
Malden, Frank James, M.B., M.R.C.S.
Proud, Frederick, M.B., M.R.C.S.
Robinson, Alfred, M.B., M.R.C.S., L.S.A.
Walker, Francis John, M.B., L.R.C.P., M.R.C.S.

BACHELOR IN MEDICINE (FINAL EXAMINATION).

Raby, Leonard, London Hospital (Second-class Honours).

PASS-LIST.

Andrews, Octavius W., M.R.C.S., St. George's Hospital.
Berwick, Geo., Coll. of Med., Newcastle-on Tyne.
Bowlan, Marcus Marwood, Coll. of Med., Newcastle-on-Tyne.
Brewis, A. S., M.R.C.S., L.S.A., Coll. of Med., Newcastle-on-Tyne.
Davis, Geo. W., L.R.C.P., M.R.C.S., St. Thomas's Hospital.
Dixson, Chas. Fred. Lyne, M.R.C.S., St. Barthol. Hosp.
East, Charles Harry, M.R.C.S., L.S.A., King's College.
Gautby, George, College of Medicine, Newcastle-on-Tyne.
Hubbard, Daniel Lovett, M.R.C.S., L.S.A., King's College.
Jaques, William, College of Medicine, Newcastle-on-Tyne.
Lavies, Harry Brandreth, M.R.C.S., L.S.A., King's College.
Laws, Cuthbert Umfreville, M.R.C.S., Coll. of Med., Newcastle-on-Tyne.
Leech, Joseph W., Coll. of Med., Newcastle-on-Tyne.
Reily, Walter Grant, Middlesex Hospital.
Richardson, Alfred Ernest, M.R.C.S., London Hospital.
Shortt, William Rushton, Coll. of Med., Newcastle-on-Tyne.
Wilson, Joseph Harwood, Owens College.

BACHELOR IN SURGERY.

Bailes, Lewis Lamb, M.B., Coll. of Med., Newcastle on-Tyne.
Berwick, George, College of Medicine, Newcastle-on-Tyne.
Bowlan, Marcus Marwood, Coll. of Med., Newcastle-on-Tyne.
Brewis, A. S., M.R.C.S., L.S.A., Coll. of Med., Newcastle-on-Tyne.
Brodrick, H. E., M.B., M.R.C.S., L.S.A., Liverpool Royal Infir.
Davis, George W., L.R.C.P., M.R.C.S., St. Thomas's Hosptal.
East, Charles Harry, M.R.C.S., L.S.A., King's College.
Gautby, George, Coll. of Med., Newcastle-on-Tyne.
Hubbard, Daniel Lovett, M.R.C.S., L.S.A., King's College.
Jaques, William, Coll. of Med., Newcastle-on-Tyne.
Leech, Joseph William, Coll. of Med., Newcastle-on-Tyne.
Lund, Theodor, M.B., Coll. of Med., Newcastle-on-Tyne.
Morton, Thomas, M.B., Coll. of Med., Newcastle-on-Tyne.
Reily, Walter Grant, Middlesex Hospital.
Stokes, John, M.B., M.R.C.S., College of Medicine, Newcastle-on-Tyne and Sheffield School of Medicine.
Wilson, Joseph Harwood, Owens College.

THE late Madame Boucicault, of Paris, has left £700,000 in charity, of which £4000 goes to the Pasteur Institute.

THE Bath Royal United Hospital has recently received under the will of the late Mrs. Maingay of Worthing a legacy of £500.

THE general annual meeting of the subscribers to the Royal Albert Asylum was held at the Chester Town Hall on the 8th inst.

THE FRENCH HOSPITAL.—The proceeds of the concert recently given at the Opera Comique in aid of this hospital in London amounted to 32,000 francs.

THERE were 17,741 fatal cases of cholera in the North-West Provinces of India during September, against 30,700 during the previous month.

THE spectacle of children carrying bottles of boiled drinking water to school with them has been an almost everyday sight in Cincinnati since typhoid fever became prevalent there.

BEQUESTS.—Mr. M. Rinkle has left the following sums to Dublin hospitals:—Mater Misericordiæ, £200; City of Dublin, £200; St. Michael's, £200; Jervis-street, £200; and St. Vincent's, £200.

VACCINATION GRANT.—Mr. A. C. Jones, M.R.C.S., of Oakham, Public Vaccinator of the Empingham district, Oakham Union, has received a Government grant for the efficiency of vaccination in his district.

A WELL-ATTENDED meeting in connexion with the Church of England Burial, Funeral, and Mourning Reform Association was held on the 12th inst. in the Chapter-room, St. Paul's-churchyard, under the presidency of the Bishop Suffragan of Bedford.

NEW WATER SUPPLY FOR SHREWSBURY. — At a meeting of the Shrewsbury Town Council on the 13th inst., it was decided to apply to the Local Government Board for powers to borrow the sum of £25,000 upon the security of the water and other rates, for the purpose of carrying out a new scheme for improving the general water supply of the town.

UNIVERSITY OF CAMBRIDGE.—At Gonville and Caius College the Thruston Prize of the value of £54, given triennially to a member of the College who has published in the course of the preceding three years the best original investigation in physiology, pathology, or practical medicine, has been adjudged to Mr. Charles Scott Sherrington, M.A., M.B., Fellow of the College.

CENTENARIANS.—Mrs. Rachel Prussic, of Spital-fields, celebrated her 106th birthday on the 10th inst. She is stated to be in such good health that she is able to go to synagogue twice on the Sabbath. A coloured man, residing in Texas, is reported to have attained the age of 117 years. The evidence of his age is afforded by a bill of sale from a slave-trader, dated 1850, and certifying that the negro in question was then eighty years old.

THE PARKES MUSEUM.—The National Society for Aid to the Sick and Wounded in War has, through Lord Wantage, made a donation of £60 to the funds of the Parkes Museum of Hygiene. The Dyers' Company have contributed ten guineas. The response to the appeal recently made has been encouraging, but further support is, we learn, greatly needed, and the most desirable form which such support can take is an annual subscription of one guinea, which qualifies for membership.

UNIVERSITY OF OXFORD.—The Warden and Fellows of Wadham College have elected Dr. James Andrew, formerly Fellow, senior physician to St. Bartholomew's Hospital, to an Honorary Fellowship of the College. The diploma of the examination in Preventive Medicine and Public Health has been awarded to Dr. G. A. Buckmaster, M.A., of Magdalen College. The diploma has been granted only once previously since the establishment of the examination.

THE LONDON TEMPERANCE HOSPITAL.—On Thursday, Dec. 8th, a largely attended *conversazione* was held in the gallery of the Royal Society of Painters in Water-Colours, Prince's Hall, Piccadilly, to commemorate the freedom of the hospital from debt owing to a recent donation of £6000 from Mr. J. J. Tustin. Another object was to arrange for the opening of all the wards, which are capable of receiving 120 in-patients. The Duke of Westminster, who is President of the hospital, could not attend, but sent a congratulatory letter with a cheque for £100.

Digitized by Google

VOLUNTEER MEDICAL STAFF CORPS.—A "Cinderella Dance" is to be given on the 19th inst. by the members of this corps at the Chelsea Town Hall, to which those holding boxes, stalls, and dress-circle tickets for the performance to be given in the afternoon of the same day at Terry's Theatre will have the privilege of admission.

THE FUTURE UNIVERSITY OF LONDON.—On the 12th inst. the course of Monday afternoon lectures at the London Institution was continued by Professor H. Morley, of University College, who gave the first of two lectures dealing with the question of a fitting University for London such as is likely in the future.

AT an inquest held at Wonford, near Exeter, on the 6th inst., on the body of an infant, the jury found a verdict of "Accidental death from an overdose of chlorodyne," and condemned in strong terms the practice of administering chlorodyne to children. The drug was administered by the mother of the infant.

PROTECTION OF THEATRE-GOERS FROM FIRE.—At the ordinary weekly meeting of the Metropolitan Board of Works on the 9th inst., the Parliamentary Committee submitted the draft of the Bill for the further regulation of theatres and music-halls, and of certain other buildings used for public purposes in the metropolis; and recommended that the Bill be deposited as required by the Standing Orders of Parliament, and that the committee be empowered to take all necessary measures for promoting its passage through both Houses of Parliament. It was reported that since the Board had charge of the theatres they had dealt with eighty-one, besides a very large number of music-halls. By this Bill it was proposed that the Board should have the power of inspecting the theatres and music-halls of the metropolis at least once a year; and having already power to make structural alterations, they asked power to see that such alterations were adhered to, and that no obstructions or extra seats should be placed in the theatres without the Board's permission. The Bill also provided for all houses being controlled by the Board where theatrical entertainments and such-like performances were held, as, for instance, "club houses." The recommendation of the committee was approved unanimously.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column are invited to forward it to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week for publication in the next number.*

BOTHAMLEY, R. BROUGHTON, M.R.C.S., L.S.A., has been appointed Medical Officer and Public Vaccinator to No. 1 District of the Bromley (Kent) Union.

BROOK, W. H. B., M.B.Lond., M.R.C.S., has been appointed House-Surgeon to the Lincoln County Hospital, vice Johnston, resigned.

CANT, W., L.R.C.P., M.R.C.S., has been appointed Surgeon to the Lincoln County Hospital.

COLLINS, HENRY BEALE, M.R.C.S., L.S.A., Surgeon, R.N., has been elected Resident Medical Officer to the St. George's, Hanover-square, Dispensary, vice Rendell, resigned.

DAVIES, JOHN T. H., M.D., M.R.C.S., formerly Resident Medical Officer to the Denbighshire Infirmary, has been appointed Surgeon to the Leicester Dispensary.

GIBBINGS, ASHLEY, M.R.C.S., L.D.S., has been appointed Professor of Dental Surgery at King's College, and Dental Surgeon to King's College Hospital.

JEFFREE, FRANK, M.B.Dur., M.R.C.S., has been appointed Assistant Medical Officer to the Stockport Infirmary.

JOSEPH, A. HILL, M.R.C.S., has been appointed Assistant House-Physician to the Royal Hospital for Diseases of the Chest, City-road, E.C.

LOWE, SEPTIMUS, M.R.C.S., L.R.C.P. Ed., has been appointed Consulting-Surgeon to the Lincoln County Hospital, on resignation of the office of Surgeon.

MARSHALL, ARTHUR L., B.A., M.B.Cantab., M.R.C.S., L.S.A., has been appointed Resident Medical Officer to the Royal United Hospital, Bath, vice Young, resigned.

OLDHAM, MONTAGUE WILLIAMS, M.R.C.S., L.R.C.P., L.S.A., has been appointed House-Surgeon to the Burton-on-Trent Infirmary, vice A. P. Trinder, M.R.C.S., L.R.C.P., resigned.

THOMSON, THEODORE, M.A., M.B.Lond., L.R.C.S.Ed., has been appointed Medical Officer of Health for the Borough of Sheffield.

WEAVER, JOHN J., M.R.C.S., L.S.A., has been appointed House-Surgeon to the Southport Infirmary, vice H. Grosvenor Shaw, resigned.

WHISTON, P. H., M.R.C.S., L.R.C.P., has been appointed Assistant House-Surgeon to the South Devon and East Cornwall Hospital, Plymouth.

Vacancies.

In compliance with the desire of numerous subscribers, it has been decided to resume the publication under this head of brief particulars of the various Vacancies which are announced in our advertising columns. For further information regarding each vacancy reference should be made to the advertisement.

ADDENBROOKE'S HOSPITAL, Cambridge. — Resident House-Physician. Salary £65 per annum, with board, lodging, and washing in the hospital.

BIRMINGHAM GENERAL HOSPITAL.—Assistant House-Surgeon. Board, residence, and washing.

CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST, Victoria-park, E.—Resident Clinical Assistant.

DORSET COUNTY HOSPITAL, Dorchester.—House-Surgeon and Secretary. Salary as House-Surgeon £70, as Secretary £10 per annum, with board and residence in the hospital.

ESSEX AND COLCHESTER HOSPITAL. — Physician. Salary £200 per annum.

LYMINGTON UNION.—Medical and Vaccination Officer. Salary £65 per annum, with the usual extra medical and vaccination fees.

SCARBOROUGH HOSPITAL AND DISPENSARY. — House-Surgeon. Salary £80 per annum, with board and lodging.

SEAMEN'S HOSPITAL SOCIETY, Greenwich, S.E. (late *Dreadnought*).—House-Physician. Salary £75 per annum, with board, furnished rooms, and attendance.

WIGAN UNION.—Medical Officer and Public Vaccinator. Salary £130 per annum, with the usual allowance for each case of successful vaccination, and such extra fees for the treatment of surgical and midwifery cases as are authorised by the orders of the Poor Law Board.

WORCESTER AMALGAMATED FRIENDLY SOCIETY. — Assistant Medical Officer. Salary £140 per annum (without residence), with a portion of midwifery fees; also £20 per annum for cab hire.

Births, Marriages, and Deaths.

BIRTHS.

BRAND.—On the 4th inst., at Invery, Driffield, East Yorks, the wife of Alex. T. Brand, M.D., C.M.Aber., of a daughter.

BROOKS.—On the 4th inst., at Beaumont-street, Oxford, the wife of W. Tyrrell Brooks, M.B., B.A., of a daughter.

BROWN.—On the 13th inst., at Claremont House, Strood, Kent, the wife of Robert Ross Brown, L.R.C.P., of a son.

HARDWICK.—On the 5th inst., at Purlands, Charing, Kent, the wife of Fredk. S. Hardwick, M.D., of a son.

RENSHAW.—On the 10th inst., at Clarendon-terrace, Stoke, the wife of Bernard Renshaw, Staff Surgeon, Royal Navy, of a son.

MARRIAGES.

HAMMOND—GRUNDY.—On the 22nd ult., at the Cathedral, Port of Spain, Trinidad, Edward Johnston Hammond, M.R.C.S., Government Medical Officer, Savana Grande, to Marian Leigh, third daughter of the late Edmond Grundy, Esq., of Greenhill, near Manchester.

MACNAMARA—WARD.—On the 8th inst., at Christ Church, New Radford, Nottingham, by the Rev. T. C. Ward, assisted by the Rev. H. Ward (brothers of the bride), the Rev. T. Pyper, Vicar, and the Rev. C. O. Miles, Hugh Winckworth Macnamara, Surgeon, Royal Navy, son of G. H. Macnamara, Esq., formerly of Uxbridge, to Charlotte, third daughter of the late William George Ward, Esq., of Newcastle-drive, Nottingham.

WESTBROOK—WELLS.—On the 7th inst., at All Saints' Church, Lewes, Richard Talbot Westbrook, M.R.C.S., to Florence Harriot Anna, only daughter of Charles Aspull Wells, Esq., of Lewes and Preston-park, Brighton, Sussex.

DEATHS.

BURROWS.—On the 12th inst., at Cavendish-square, W., Sir George Burrows, Bart., M.D., F.R.S., Physician in Ordinary to the Queen, Consulting-Physician to St. Bartholomew's Hospital, late President of the Royal College of Physicians, in his 87th year.

COLE.—On the 7th inst., at Lymm, Cheshire, Henry Cole, M.R.C.S., aged 59.

GREENWOOD.—On the 5th inst., at his residence, Two Mile Ash, Horsham, T. Bryan Greenwood, M.R.C.S., L.S.A., formerly of Horselydown, S.E., aged 77.

KERR.—On the 10th inst., at his residence, Croft House, Crawshawbooth, near Manchester, James Kerr, L.S.A.L., aged 76.

PIGGOT.—On the 10th inst., Allen Piggot, M.R.C.S., L.R.C.P., of Beckenham, Kent, eldest son of Jas. A. Piggot, of Beckingham, Essex.

WILDE.—On the 8th inst., at Swineshead, Lincolnshire, after a few days illness, Fredk. Wilde, M.R.C.S., aged 30.

N.B.—*A fee of 5s. is charged for the Insertion of Notices of Births, Marriages, and Deaths.*

Notes, Short Comments, & Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

All communications relating to the editorial business of the journal must be addressed "To the Editors."

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news-paragraphs should be marked and addressed to the Sub-Editor.

Letters relating to the publication, sale, and advertising departments of THE LANCET *to be addressed "to the Publisher."*

We cannot undertake to return MSS. not used.

CRUELTY TO CHILDREN.

To the Editors of THE LANCET.

SIRS,—Will you kindly permit us to bring before your readers the claims of the work in which we are engaged in the London Society for the Prevention of Cruelty to Children. The following facts speak for themselves.

In our three years' history, since our founding at the Mansion House in July, 1884, we have dealt with 762 more or less cruel people, for the most part by moral influence. In 132 worst cases, many almost incredible, we have had resort to the law, and have obtained 120 convictions. Of the total number of 762 cases, we find that 333 were cases of injuries inflicted by assault, 81 of starvation (some of these of farmed-out babies and children insured), 130 of dangerous neglect, 32 of desertion, 70 of cruel exposure to excite sympathy in the streets, and 116 of other wrongs. Our efforts have not been confined to London, but have extended to many parts of the country. We do not interfere with mere parental indiscretion, but only with deeds of cruelty which render child-life unendurable, twenty-five cases ending with the victims' death. When punishment is inflicted, it is always followed by indirect, but real, supervision.

At this child-season of the year, we feel that our work must appeal very powerfully to all generous hearts. The following ladies will be glad to receive subscriptions:—The Countess of Iddesleigh, 23, Manchester-square; Lady Henderson, 4, Gledhow-gardens; Lady Whittaker Ellis, Buccleuch House, Richmond. Also at the office subscriptions will be gratefully received.—We are, Sirs, yours obediently,

R. RUTHVEN PYM, Treasurer,
BENJ. WAUGH, Hon. Sec.

Office of the Society, 7, Harpur-street, Bloomsbury.

Peripatetic.—Hoblyn's Dictionary of Terms used in Medicine and the Collateral Sciences, published by Whittaker & Co., Paternoster-square.

"ROUGH-AND-READY MEDICAMENTS."

To the Editors of THE LANCET.

SIRS,—It may interest Brigade-Surgeon Curran to know, that, on the evening before his interesting letter under the above heading appeared in THE LANCET, Dr. Howship Dickinson, at a dinner at Prof. Philipson's at Newcastle-upon-Tyne, related the case described by Sir Astley Cooper with reference to the patient with "bow shins," and told us how the late Mr. Hilton had told him that the patient eventually came under his care suffering from malignant growths of the cicatrices in both legs. This seems worth recording; for besides the curious coincidence of the double mention of the case, it is of special interest in connexion with Mr. Hutchinson's paper on Arsenic Cancer, read on Tuesday, the 6th inst., at the Pathological Society, and reported in your issue of to-day.

I am, Sirs, faithfully yours,

Holly House, Sunderland, Dec. 10th, 1887. JAMES MURPHY.

"TREATMENT OF ECZEMA AND PSORIASIS."

To the Editors of THE LANCET.

SIRS,—As the treatment of the above diseases is at present being discussed in your journal, and as I have successfully treated several hundred cases of both diseases during the past twelve years in the following manner, I beg to forward it to you for publication, should you think it worthy of a place in your journal.

In acute eczema I have found nothing to excel the oxide of zinc ointment as a local application, whilst the serum is still exuding. As this dries, equal parts of zinc ointment with vaseline or lanoline to be kept constantly applied to the diseased surface, forbidding water in any shape or form; and I may say at once that to this do I attribute a very great share of the success of the treatment, the part to be washed, only when absolutely necessary, with milk and warm water in equal parts. To allay the irritation in chronic eczema, from one to seven minims of pure carbolic acid to an ounce of the equal parts of zinc ointment and vaseline; all scales and dirt of any kind to be gently removed with the eye of a large needle (I use a small director). The impetiginous form I treat in the same way, mopping up any discharge with cotton-wool, which is far more successful than by poultice or bathing with warm water. To sum up: Keep the diseased surface dry, and constantly greased with the preparations mentioned; treat the constitution generally; try to get every organ of the body to perform its natural function. Diet plain and fresh, with a liberal allowance of vegetables and fruits; the less alcohol in any shape or form the more rapid the recovery, as also tea and coffee.

Few are the cases of psoriasis that will not yield to arsenic internally and carbolic acid externally, with alkaline baths every other day or twice a week. With regard to the external application, it is best to commence with a strength of from two to five minims to the ounce, and gradually increase till in some cases the strength of the glyc. acid. carbol. (B.P.) has been reached. In only about 1 per cent. has the carbolic acid been found to blacken the skin or in any way to act injuriously, the worst case of abnormal pigmentation being the one I reported in your columns three years ago.

I am, Sirs, yours truly,

Jermyn-street, S.W., December, 1887. W. R. CULLING.

To the Editors of THE LANCET.

SIRS,—Will Dr. Myrtle kindly give the preparation of tar he most approves, and also the strength of the quinine lotion he usually employs? His article and Sir Andrew Clark's recent one on Chlorosis are types of those most welcome to busy practitioners.

I am, Sirs, yours obliged,

Dec. 12th, 1887. CLUB.

M.R.C.S.—There is no inflexible rule. It is better to follow the custom hitherto observed in the district.

Mr. A. C. Morton.—We referred to all papers to which our remarks would justly apply.

Dr. J. D. Malcolm.—The paper is marked for insertion.

DIPHTHERIA DURING PREGNANCY.

To the Editors of THE LANCET.

SIRS,—In an annotation in your last issue I observe an extract from the *Russkaya Meditsina*, in which Dr. Korotkevich mentions that he has only been able to find four cases of diphtheria during pregnancy reported. I was not aware that it was so rare in pregnant women; but as it appears to be so, it may interest your readers to hear of an additional case.

In September last a woman about seven months advanced in pregnancy came to my house to consult me with well-marked diphtheria, the uvula and both tonsils being covered with the characteristic false membrane. She was very feeble. Two days later I was summoned on account of urgent symptoms. As I was engaged with a midwifery case, a friend and neighbour, who saw the woman for me, performed tracheotomy; but the patient died the same evening.

I am, Sirs, yours faithfully,

Bath, Dec. 12th, 1887. W. N. HEYGATE.

M. P.—The qualification mentioned does not carry the title of surgeon. Our correspondent should get a surgical qualification.

Dr. Bell Taylor.—Very shortly.

VOLUNTARY BOARDERS IN LUNATIC ASYLUMS.

To the Editors of THE LANCET.

SIRS,—In reply to the question as to voluntary boarders, will you allow me to say that both private asylums and registered hospitals for the insane can accept as voluntary boarders patients who within five years have been under medical certificates; and that registered hospitals, such as Bethlem, can receive as such any patients who voluntarily place themselves under care, provided they are not so insane as to be unable to form a judgment, or are otherwise only fit to be placed under certificates. The Commissioners in Lunacy see such patients on their visits, and advise in many cases whether such cases should be certified or allowed to remain as boarders. In Bethlem we have from ten to fifteen such boarders, and find that they fall into the regulations very well.

I am, Sirs, yours truly,

Bethlem Hospital, London, S.E., Dec. 12th, 1887. GEO. H. SAVAGE.

Digitized by Google

INTERESTING MIDWIFERY CASE.

To the Editors of THE LANCET.

SIRS,—I read the other day in your issue of Oct. 15th, Mr. Borham's interesting account of a labour in which head, hand, and cord presented, and where he succeeded in delivering a living child. I had never seen a case of a similar kind in practice before, but yesterday, the 7th inst., I met with the following complication of presentation, which is similar to, but, I think, even more curious and rare than, Mr. Borham's case. Mrs. W——, a negress, was being attended in labour with her ninth child by a midwife. The labour had continued for twenty-four hours, during which time the pains had been slight, but regular, and the membranes had been ruptured for twelve hours. At this stage I was sent for hurriedly. I was informed on arrival that fifteen minutes before, while Mrs. W—— was passing urine, the cord had come down, and also that the child was "lying across." I found a loop of cord, about four inches in length, hanging external to the vulva. It was quite cold and pulseless. The mother stated that she had felt no movement of the child since the waters had come away, twelve hours before. On examining, I found the child's right foot presenting alongside the head and between the head and the right acetabulum. The pelvis was capacious, as is generally the case in the negress, and I was able, with great ease and with the introduction into the vagina of only two fingers and the thumb, to turn and deliver a dead male child of fair average size. The cord was not unusually long, but I did not measure it. There was no history of fall or accident in this case.

I am, Sirs, yours truly,

Tobago, W.I., Nov. 8th, 1887. JOHN P. TULLOCH, M.A., M.B.

Mr. Hackett might apply to the Secretary of the Brussels Graduates' Association, The Limes, St. Mark's-road, North Kensington.

Alpha had better apply to the Secretary of the Society which gives the subject its special attention.

A Constant Reader will see by referring to our last issue that we have noticed the matter.

VACCINATION NOTES.

To the Editors of THE LANCET.

SIRS,—It may be of service to the profession to put on record the two following cases.

CASE 1.—J. W. L——, aged about seventeen years, came before me to be examined and vaccinated before appointment as telegraph messenger. He was never vaccinated as an infant, but had had a severe attack of small-pox during the epidemic here in 1881-2, which left him liberally marked. I vaccinated him on Saturday, Nov. 19th, 1887, in four places, all of which I found four days after to have taken well.

CASE 2.—A. B——, aged thirty-four. On Nov. 21st, 1887, I revaccinated this patient, and four days later found two successful takings (I had put on two only). He was never vaccinated as an infant, but in January, 1886, I vaccinated him myself in two places, which took severely, leaving deep marks, with high fever, enlarged axillary glands, &c., necessitating confinement to the house.

In Case 2, I only report a not uncommon instance, but the time between a severe vaccination in January, 1886, and a second successful vaccination in November, 1887, seems short. Case 1, however, seems to open up a field for thought. 1. Was J. W. L. liable before revaccination to another attack of small-pox? 2. Granted, as I believe, that vaccinia prevents variola, does variola prevent vaccinia? 3. But how much of the variolla one sees in children is variola modified by non-efficient vaccinia?

I am, Sirs, yours truly,

Rochdale, Dec. 5th, 1887. WILLIAM STANWELL.

Doubtful.—Not under Clause 16. For registration of foreign degrees under this clause it is necessary that they should have been held prior to the passing of the Act. In the course of time, under other clauses, certain foreign and colonial degrees will be registrable.

Mr. J. G. Leeson.—The Australasian Medical Directory, published by Baillière, Tindall, and Cox, King William-street, Strand, will give the information desired.

A WARNING.

To the Editors of THE LANCET.

SIRS,—Will you kindly grant me space to warn members of the profession against a man who gives the name of Adams, and introduces himself with my name and recommendation to sell various kinds of cloth? He gives a false address—Dalkeith, near Edinburgh. The police have been trying to find him for some time past. As I have heard of him again to-day, I think it well to mention these facts.

I am, Sirs, yours faithfully,

Grafton-street, Piccadilly, Dec. 13th, 1887. DYCE DUCKWORTH.

Mr. William Watson.—We have no means of identifying the "Dr. Clark" mentioned in the report.

Ether.—Mr. Coxeter of University-street will no doubt give the required information.

LONG SURVIVAL OF TRIPLETS.

To the Editors of THE LANCET.

SIRS,—It may interest your readers to learn that I am attending a gentleman, aged thirty-one, whose two sisters, born on the same day that he was, are alive and well. I have never previously heard of triplets all living to any considerable age.—Yours truly,

F. TAYLOR SIMSON, L.R.C.P. Lond.

Lavender-hill, S.W., Dec. 14th, 1887.

EPSOM COLLEGE.

To the Editors of THE LANCET.

SIRS,—The annual report of Epsom College has just been sent to the governors, and I find that it contains certain proposed alterations in the rules and bye-laws which, I suppose, were carried at the annual meeting. If so, I should like to point out that all these alterations are not made in favour of the parents. Why should the parents have to pay for school books which become of no value after their sons have used them? The tendency of the Council is to raise the expense to parents sending their sons to Epsom. The prospectus speaks of £52 10*s.* per annum; but I found that it came to nearly £70 per annum for my son, and with the cost of books added it may come to £75. Then, again, why should a foundation scholar elected by the governors be refused admission on account of his character? Surely, the Council before admitting the boy on the list of eligible candidates might make some inquiry as to his character, so as to prevent the child being thrown back on the widow after all her anxiety and expense in procuring his election. I am well satisfied with the progress my son made at Epsom, and with the attention of the masters; but I do say the Council are forgetting the reasons for which the College was established—viz., to enable medical men to have their sons educated at a reasonable cost.

I am, Sirs, yours obediently,

December, 1887. A MEDICAL PRACTITIONER.

Surgeon.—There is no such thing, strictly speaking, as a legally qualified midwife. Various hospitals give training and certificates in midwifery, as the City of London, Queen Charlotte's and York-road. But there is as yet no legally constituted authority to regulate the education, examination, and qualification of midwives. Meantime, the best thing our correspondent can do for the "trustworthy and intelligent" nurse is to send her to some such institution.

House-Surgeon is obliged to make post-mortem examinations and attend and give evidence at inquests without receiving fee.

IMPOTENCE AND DIABETES.

To the Editors of THE LANCET.

SIRS,—I think the following case is of some interest in respect to the question of impotence and diabetes.

William A——, aged seventy, came under my care in November with a carbuncle on the back, which he had had for three weeks. On testing the urine it was found to contain an abundance of sugar. Symptoms of diabetes—i.e., thirst and the passage of a large quantity of urine—had been noticed for about four months; but it is probable that the diabetes had been present even longer. The patient had been married four times, and the last wife, who is still alive, was recently confined of twins.

I am, Sirs, yours faithfully,

Stroud Hospital, Dec. 6th, 1887. M. C. MOXHAM.

Epsilon.—Art. 156 states that no appointment shall be made under the General Consolidated Order "unless an advertisement giving notice of the consideration of such appointment shall have appeared in some public paper by direction of the guardians at least seven days before the day on which such appointment is made, provided that no advertisement shall be necessary for the appointment of an assistant or temporary substitute."

Dr. James Oliver.—Yes, the shorter paper.

TREATMENT OF TETANUS BY NITRITE OF AMYL: RECOVERY.

To the Editors of THE LANCET.

SIRS,—I was much struck, in a case of traumatic tetanus which I had under treatment this year, by the great relief given by inhalations of nitrite of amyl. The patient was treated with bromide and chloral, with the addition of morphia. After the second day, and when a paroxysm seemed coming on, he used the amyl freely with great relief, usually dropping off to sleep after two or three inhalations.

I am, Sirs, yours faithfully,

South Tottenham, December, 1887. GEO. B. BEACH.

Dr. T. Maccall.—We shall be glad to receive a specimen of the instrument when ready to be issued.

BALLIN'S FUR RESPIRATOR.

To the Editors of THE LANCET.

SIRS,—I beg the favour of your correction of the notice of the above respirator, which appeared in THE LANCET of Dec. 3rd. The leather part of this respirator is perforated with minute holes, so that the air is inhaled easily through the fur; and it is so prepared that it can be washed in cold water without being injured.

I am, Sirs, yours faithfully,

Aldersgate-street, Dec. 12th, 1887. J. S. BALLIN.

CORRIGENDA.—In Mr. Pemberton's letter on the Treatment of Cancer, published last week, for "or contamination of the adjacent glands" read "or contaminating the adjacent glands"; and in Mr. Jessett's letter on the same subject, for "In some cases of cancer of the uterus the patients have expressed themselves as 'free' from pain" read "patients have expressed themselves as *freer* from pain."

Lectures
ON
FIBROID DEGENERATION AND ALLIED LESIONS OF THE HEART, AND THEIR ASSOCIATION WITH DISEASE OF THE CORONARY ARTERIES.

By JOHN LINDSAY STEVEN, M.D.,
ASSISTANT TO THE PROFESSOR OF CLINICAL MEDICINE IN THE UNIVERSITY OF GLASGOW; ASSISTANT PHYSICIAN, GLASGOW ROYAL INFIRMARY; AND ASSISTANT TO THE LECTURER ON PATHOLOGY IN THE WESTERN INFIRMARY OF GLASGOW.

LECTURE III.
SUMMARY OF CONCLUSIONS.

THE somewhat exhaustive study which we have made of the varieties of heart disease described in the foregoing lectures naturally leads me to formulate the following conclusions, which I think will be fully borne out by the facts already passed in review:—1. That a very sharp distinction must always be drawn between true atrophic fibroid degeneration and interstitial myocarditis; that, though similar in their results, they are quite different in their mode of production, and that the former is a much more common lesion than the latter. 2. That we should not be satisfied with merely opening the heart and examining the endocardium and valves, as is too often the case at post-mortem examinations, but that in all cases the muscular tissue, by numerous incisions parallel to the surface, should be carefully investigated. 3. That the anastomosis of the coronary arteries is not so free as to be of any practical moment (especially when the vessels are diseased) in preventing the occurrence of fibroid degeneration or of infarction of the heart as a result of obstruction of their branches. 4. That the influence of a morbid state of the coronary arteries must be taken into account in considering all diseases of the heart, but especially those of the myocardium, and that no examination of the heart can be regarded as complete which does not include a careful investigation of the state of these vessels. 5. That, though admittedly difficult, the possibility of diagnosing fibroid degeneration and infarction of the heart should always be kept in sight, and that by carefully passing in review the whole symptomatology and pathology of a given case of cardiac disease, a correct opinion in this regard may probably be arrived at.

RECORD OF CASES OF FIBROID DEGENERATION, INFARCTION, AND FATTY DEGENERATION OF THE HEART ASSOCIATED WITH A DISEASED CONDITION OF THE CORONARY ARTERIES.

It now only remains for me to briefly record the cases which I have investigated, and upon the examination of which the opinions I have already expressed are mainly based. For the opportunity I have had of examining many of the following cases, and for liberty to make use of the pathological records in connexion with them, I have in this place to express my obligations to my friend Dr. Joseph Coats, lecturer on Pathology in the Western Infirmary of Glasgow.

CASE 1. *Slight fibroid and fatty degeneration of left ventricle, with atheroma of the coronary arteries.*—Duncan C——, aged fifty-two, was admitted to Dr. Anderson's wards of the Western Infirmary on Jan. 28th, 1885, complaining of a common cold of a week's duration, with a sense of uneasiness in the epigastrium, and several attacks of severe pain in that region. There was some tenderness and enlargement of the left lobe of the liver; and two days after his admission he was suddenly seized with severe pain of the nature of angina pectoris, and died in about ten minutes.

A post-mortem examination was made on Feb. 1st, 1885, of which the following is a summary: Flabby and dilated heart; passive hyperæmia of lungs and other organs. With regard to the heart, it was found to be somewhat enlarged, weighing 12½ oz., and the right ventricle was considerably dilated. The cavities contained much fluid blood, and almost no clot; the mitral orifice admitted three fingers, the tricuspid six. The muscular tissue, especially that of the right ventricle, was pale, and to the touch it felt flabby. The valvular structures were normal. The internal coat of the aorta presented patches of fatty degeneration. On careful examination of the coronary arteries many small areas of atheroma were discovered, but the vessels were quite pervious. Throughout the muscular tissue of the left ventricle numerous small yellowish spots were discovered, and on its posterior wall near the apex there was a distinct fibrous area about the size of a threepenny-piece, with around it evidences of slighter degrees of the same thing. There was also a generalised, but by no means extreme, fatty degeneration of the muscular tissue. The kidneys presented nothing remarkable. On microscopic examination of the fibrous area, it was found to consist of delicate wavy lines of connective tissue, with here and there a granular appearance as if nuclei were scattered through it. In the midst of the fibrous tissue remains of muscular fibres were present; these fibres became atrophied at their extremities, and were prolonged into delicate, wavy fibrillæ, which were ultimately lost in the surrounding connective tissue. The appearances were strikingly suggestive of an atrophy of the true muscle substance having taken place. On staining with picro-carmine, the affected patch stained of a deep-red colour.

CASE 2. *Slight fibroid degeneration of left ventricle; coronary arteries pervious, but presenting evidence of hypertrophy of middle coat; granular kidneys.*—Alex. K——, aged fifty-three, a plumber, was treated in Dr. Joseph Coats' ward of the Western Infirmary. The clinical history was that of chronic Bright's disease, with two attacks of generalised œdema, one of which occurred during his residence in hospital, when fatal uræmic convulsions supervened.

The following is a summary of the post-mortem examination: Granular kidneys (atrophy of cortex); enlarged left ventricle of heart; dilatation of lateral ventricles of brain; œdema of membranes. The heart presented great hypertrophy of the left ventricle, and weighed 20 oz. The muscular tissue was of good colour and consistence. On careful examination a small area of fibroid change about the size of a split pea was discovered in the anterior wall of the left ventricle. The coronary arteries, so far as could be discovered by the naked eye, were quite healthy and pervious. A typical "soldier's spot" was present on the surface of the right ventricle, and it was also noted that the pericardium presented linear, opaque, white areas of thickening, which followed the course of, and seemed to surround, the branches of the coronary arteries. The fibroid patch and the pericardial thickenings were reserved for microscopic examination. The kidneys were extensively diseased; the cortex was much atrophied and infiltrated with round cells; uric acid infarctions were present in the pyramids. On microscopic examination the fibroid patch presented characters precisely similar to those observed in the last case. In several of the sections minute arteries were observed, and these presented very obvious signs of disease. The middle coat was very greatly hypertrophied, but no sign of the so-called arterio-capillary fibrosis could be detected. In the thickened pericardium the arteries also showed distinct thickening of the middle coat, but no exaggeration of the external.

CASE 3. *Fibroid patch in left ventricle; widespread arteritis deformans; coronaries pervious, but hypertrophy of middle coat of arterioles.*—Mrs. M——, aged thirty-five, was admitted to Dr. Anderson's wards on Nov. 3rd, 1886, complaining of palpitation and dyspnœa. The symptoms had been present for eleven years, more or less. There was a double aortic murmur, with dulness over the manubrium sterni and purring tremor in the supra-sternal notch. Hæmoptysis occurred on several occasions, and dyspnœa was always distressing.

On post-mortem examination the case was found to be one of widespread arterio-sclerosis (arteritis deformans); but with the naked eye the coronary arteries were found to be flexible and healthy throughout, with not a trace of atheromatous deposit to be seen, even in the finer ramifications. The left ventricle was greatly hypertrophied, and in the apical region a very typical patch of fibroid change, about half-an-inch in diameter, was discovered. It was depressed, white, and glistening or tendinous in appearance. On microscopic examination the fibroid patch presented the characters already described. The arterioles, however, in and around the sclerosed area presented marked hypertrophy

Digitized by Google

of the middle coat, and in some it was also thought that there was slight thickening of the internal coat as well.

CASE 4. *Multiple areas of fibroid disease and softening due to embolism of coronary arteries; extensive aortic disease.*—Mrs. S——, aged thirty-eight, was admitted to Dr. Anderson's wards on Feb. 6th, 1885, complaining of cough, dyspnœa, and profuse expectoration of about one month's duration. There was a history of bygone rheumatic pains in the joints. Six years previously she had suffered from similar symptoms after a confinement, and the fatal attack began after her last labour. There was passive congestion of all the organs, which continued till death, and well-marked signs of aortic disease.

The heart was enlarged, weighing 17 oz.; the hypertrophy was general, but was specially well marked in the left ventricle. The aortic valve was quite incompetent, and much disorganised—the curtains being greatly deformed and the seat of massive vegetations. In some places the segments of the valve were distinctly torn. Infarctions were present in the lungs, and other organs. On more minute examination of the heart, numerous small areas of fibroid change were found scattered throughout the substance of the wall of the left ventricle. Most of these areas had the typical shining and tendinous appearance, and were depressed beneath the level of the cut surface, and irregular in outline. At two places were observed more recent patches of a brownish or hæmorrhagic appearance, and distinctly soft in consistence. The characters observed in this case very decidedly suggested multiple embolism as the cause of the condition. On microscopic examination the distinctly fibroid areas presented features quite similar to those already described, but in the recent patches the histological characters were quite in keeping with the supposition that they had been caused by an embolic process—that is to say, in the recent areas the bundles of muscular fibres, while they preserved their bulk and general outline, had lost the opaque and striated appearance of the healthy bundles; the individual fibres looked as if they had run together more or less, and they had throughout a homogeneous, glistening, transparent character—coagulation necrosis. The bundles of coagulated muscular fibres were separated from one another, just as in the case of normal bundles, by strands of fibrous tissue. These appearances were observed in one of the patches which had been cut in transverse section, and on examination of another portion cut in longitudinal section precisely similar changes were made out. The fibres were evidently coagulated, and were in many places undergoing absorption. The absorbed fibres were replaced by very beautiful fibrous tissue, and so long as any necrosed tissue could be seen it presented the translucent, bright-yellow appearance already adverted to. The affected patch was quite irregular as regards its junction with the surrounding healthy tissue, and here and there isolated normal fibres might be seen in the midst of the necrosed area. At the margins of the areas in some of the sections numerous engorged veins were seen, with slight exudation of round cells into the surrounding tissues. The muscular nuclei had disappeared from the coagulated fibres

This case seemed to me to be most important as showing the relationship existing between the acute infarction of the heart wall and the chronic fibroid change; and, clinically, it also points to a possible cause of rapid heart failure in cases of severe aortic disease.

CASE 5. *Multiple areas of fibroid degeneration and softening, probably embolic; atheroma of coronary arteries.*—John C——, aged sixty-two, died in one of Dr. Tennent's wards on March 20th, 1885. He had been suffering from cough, spit, dyspnœa, and palpitation, with pain across the chest, and œdema of the ankles. On Feb. 24th there was complaint of pain and numbness in the left leg, with painful swelling of the left thigh. On Feb. 28th he was paralysed on the left side of the body and the right side of the face. On March 7th there was a second attack of facial paralysis, and on the 20th he died.

On examining the basal vessels of the brain, the right posterior cerebral was found to be cylindrical, being distended by a dark plug, which extended to its bifurcation, where the thrombus became rather pale. The obstructed vessel crossed over the right peduncle and the third nerve; and the peduncle was much softened. Embolic infarctions were also present in the kidneys and spleen. The heart was somewhat enlarged and dilated, weighing 13½ oz.; and there were thrombi in the apex of the left ventricle. The valvular structures presented opacities and occasional calcareous infiltration. On more particular examination, it was found that the organ presented patches of fibroid change, with a well-marked area of softening in the substance of the left ventricle near the apex: the morbid condition of the muscular tissue was in all probability due to embolism of the smaller branches of the coronary arteries. The area of softening at the apex of the left ventricle was about the size of a sixpence; and on being cut into was seen to be semifluid in consistence and brown in colour: the morbid area could be easily differentiated from the surrounding healthy tissue by being depressed below its level. About the middle of the posterior wall of the left ventricle and corresponding pretty nearly in situation with the point of attachment of the musculi papillares of the posterior curtain of the mitral valve, there was an area about the size of a shilling of well-marked tendinous change, which was hard and tough on section, and which extended through the entire thickness of the ventricular wall. The coronary arteries were perhaps slightly dilated and tortuous, and presented here and there small patches of atheroma similar to those observed on the valvular curtains; but, as far as they could be traced, all the branches were pervious. The area on the posterior wall was in the region supplied by a terminal branch of the right coronary artery, that at the apex in the region of the descending branch of the left. Sections were made from several of the morbid areas in this heart, and on microscopic examination the appearances were found to be very similar to those described in connexion with Case 4—i.e., the softened areas presented well-marked signs of coagulation necrosis, and the fibroid patches showed the wavy strands of fibrous tissue. It was also noted that around the recent patches there was great dilatation with engorgement of the capillaries and veins; the arteries had thickened walls, were not engorged, and presented in their interiors a distinct fibrinous stroma, in the meshwork of which a few blood-corpuscles were entangled, this appearance being very suggestive of the presence of thrombosis in the smaller arterial branches. In addition the following features were also observed: (1) In some places a distinct cellular infiltration was observed, as if slight inflammatory reaction had been set up; (2) here and there large round cells not unlike compound granular corpuscles were seen, and it was thought that possibly these cells may have had some relationship to the muscular nuclei; and (3) in some sections, as well as the capillary engorgement, a distinct infiltration of the interstices of the tissues with red blood-corpuscles, a circumstance quite in keeping with the view that the condition was the result of embolic infarction, was noticed.

CASE 6. *Extensive fibroid degeneration of left ventricle, with extreme calcareous disease of coronary arteries.*—Duncan G——, aged seventy-four, died in one of Dr. H. C. Cameron's wards on Feb. 25th, 1885. He had been admitted on Feb. 12th on account of difficulty of micturition, which had been present in a more or less severe form for about eight years. On the 21st, on trying to get out of bed, he fell on the floor, and seemed to have lost the power of his right side to some extent; the left shoulder was also very painful. On the 24th breathing became stertorous; there seemed to be some loss of power in both arms and in the left cheek. In a few hours he died.

At the post-mortem, on examination of the head, no recent lesion could be discovered in the brain; but there was extreme atheroma of both middle cerebral arteries. The heart was considerably dilated, weighing 17¾ oz.; and on careful examination a most striking and extensive fibrous transformation of the muscular substance was found in the lower two-thirds of the posterior wall of the left ventricle. The greatest length of the patch was three inches and a half, and breadth one inch; its margin was irregular, and it stretched obliquely downwards from a point a little above the middle of the outer wall of the ventricle towards the apex. A calcareous plate causing constriction of the left coronary artery was discovered at its point of bifurcation into the descending and circumflex branch; the right coronary artery was also atheromatous.

It is interesting to note that at the time of the post-mortem examination this patch was not discovered; and it was only on more detailed investigation, after the case had been demonstrated by Dr. Joseph Coats to his pathological class, that I found it to be present. Its presence could not have been guessed by simple inspection either of the endocardial or pericardial surfaces.

CASE 7. *Extensive fibroid degeneration of the left ventricle, with extreme disease of the coronary arteries.*—Robert W——, aged sixty, a traveller, was admitted to Dr. Tennent's wards on Feb. 13th, 1885, suffering from dyspnœa, hæmoptysis, and slight œdema of both lower extremities. There were distinct evidences of passive congestion of the lungs, and well-marked ventricular-systolic aortic and ventricular-systolic mitral murmurs were made out on auscultation, as well as accentuation of the second sound at the base. During a former residence in the hospital, December 1884, he had suffered severely from angina pectoris, which also caused much distress during his last illness. He was also occasionally seized with severe attacks of dyspnœa, during which the whole body became very cold. He died on May 22nd, 1885.

The following is a summary of the post-mortem examination: Great atheroma of aorta, with thrombosis; atheroma of the coronary arteries; fibroid transformation and dilatation of the ventricles of the heart; plugs in the pulmonary artery; infarction of the kidney. The heart was enormously enlarged, but the weight of the organ has not been recorded. The left ventricle was greatly distended, as was also the right, but to a less extent. In the right auricle and ventricle were several globular vegetations—a large one in the auricle yielding a brown juice when cut into. The first part of the aorta was in an extreme state of atheroma, with calcareous infiltration almost continuous. The wall of the left ventricle presented in various places a remarkable atrophy, accompanied by a fibrous transformation of its muscular substance. Both coronary arteries were extensively diseased. On more detailed examination the following facts with regard to the fibroid degeneration were made out. The left or posterior coronary artery presented well-marked atheroma and calcareous change, especially in its descending branch. Just beyond the origin of this branch the lumen of the vessel was very considerably narrowed (being converted into a rigid calcified tube of fully an inch in length); and on laying open the artery, an adherent reddish clot, which caused additional obstruction, was discovered. The distal branches of this vessel were also considerably narrowed and calcified. In the ventricular septum in the area supplied by this vessel there was a large patch of typical fibroid degeneration, two inches long by one broad. The glistening tendinous character of the patch was most striking towards the centre, whilst at the margin the fibrous metamorphosis insinuated itself quite irregularly between the healthy muscular fibres; the change caused distinct loss of bulk, and the cut surface of the morbid area was distinctly concave. Here and there the morbid surface presented a reddish streak, as if due to an engorged vessel or a hæmorrhagic extravasation. The relationship to the diseased vessel was in this case exceedingly well marked. In the posterior wall of the left ventricle a long, ill-defined, and diffused strand of similar change, passing downwards towards the apex from the insertion of the musculi papillares, was discovered. A similar patch was also present in the anterior wall. The right coronary artery was also extensively diseased and much dilated, but it contained no adherent clot, although there was plenty of loose débris. There was also extensive fatty infiltration of the organ.

CASE 8. *Slight fibroid disease of left ventricle, with generalised fatty degeneration; serious disease and obstruction of coronary arteries.*—James S——, aged forty-nine, was admitted to Dr. Gairdner's wards on March 13th, 1885, and died on June 18th of the same year. In December, 1884, he began to suffer from pain across the breast on any exertion, accompanied by attacks of shortness of breath. It was found to be a case of aortic regurgitation, with dilatation of the arch (possibly aneurysm). There was hypertrophy of the left ventricle, and symptoms of well-marked angina pectoris, with apparent extension of neuralgic sensations into the right lower limb, where distinct evidences of regular gout were observed. Ventricular-systolic and ventricular-diastolic murmurs were heard over the aortic area; the vessels were tortuous, and there was dull percussion over the manubrium sterni. Latterly there was a considerable amount of blood in the expectoration, with marked orthopnœa and acceleration of the pulse and respiration. There was no history of previous serious illness, but the patient had been a drinker.

Summary of post-mortem: Dilatation and hypertrophy of the left ventricle, with contraction of the aortic curtains and extreme atheroma of the aorta; passive congestion of the lungs; granular kidneys; deposits of urate of soda in the metatarso-phalangeal joints. The heart was very much enlarged, weighing 27½ oz., and the arch of the aorta was somewhat dilated. The tricuspid orifice passed five, and the mitral three, fingers. The aortic valve was quite incompetent, from its curtains being involved in the atheromatous disease. The aorta presented an extreme state of atheromatous change, and the muscular tissue of the heart was very pale, and presented considerable fatty degeneration of the left ventricle. The coronary arteries were pervious, but much diseased in several places. In the first part of the descending branch of the left coronary a calcareous plate of stony hardness was discovered; it was half an inch long by one-eighth of an inch broad, and it emitted a ringing sound on being struck with the probe; the orifice of the vessel was somewhat rigid and slightly narrowed. The orifice of the right coronary artery was greatly contracted, so that only a very fine probe could be passed through it. Beyond the obstructed orifice there was great dilatation and considerable tortuosity of the vessel; in its interior there was broken-down blood clot, at places slightly adherent to the vessel wall. In the posterior wall of the left ventricle slight traces of fibroid change, extending over an area of about the size of a shilling or more, and showing the usual microscopic characters, presented themselves; in many places, too, the muscular fibres showed great granularity, obviously due to fatty degeneration. This slightly fibroid area, the only one discovered, was in the area of distribution of the terminal branch of the right coronary artery.

(To be concluded.)

Clinical Lectures
ON
DISEASES OF THE EYE.

Delivered at the Nottingham and Midland Eye Infirmary,

BY C. BELL TAYLOR, M.D., F.R.C.S.,
HONORARY SURGEON TO THE INFIRMARY.

LECTURE VI.

GLAUCOMA.—(*Concluded.*)

GENTLEMEN,—In a former lecture on the Use and Abuse of Mydriatics,[1] I called your attention to the great danger attendant upon the instillation of atropine in all cases of possible or threatened glaucoma, and it becomes interesting now to inquire in what this danger consists. One would think *a priori* that atropine, from its sedative influence and power of checking secretion, would be a useful remedy in glaucoma, and so it would, but for its power of dilating the pupil. It is this purely mechanical action, this crowding of the iris into the angle of the anterior chamber—the main outlet for fluids from the eye,—which is the source of all the danger attending the employment of mydriatics in glaucoma. I pointed out also that in doubtful cases it was safest to use cocaine—an alkaloid which checks secretion even of tears, relieves pain, diminishes the calibre of bloodvessels, reduces tension, and, although an efficient, is still, compared to atropine, a feeble and non-persistent, mydriatic. Since then I have demonstrated over and over again that eserine, although impotent, or nearly so, as a myositic against atropine, duboisine, daturine, hyoscyamine, and the more powerful mydriatics, possesses complete control in this respect over cocaine, and that the two in succession or combination may not only be safely employed, but in this form will probably constitute one of the most valuable adjuncts to our remedies for the treatment of glaucoma. Let me illustrate my meaning. If the iris, when dilated, should be so fixed by adhesions that it could not contract, eserine, powerless to stretch apart the fibres of the ligamentum pectinatum, by reducing the size of the pupil, would probably do nothing but harm by its irritant action; and if the pupil should be contracted and occluded by adhesions, so that atropine could not crowd out the angle of the anterior chamber by dilatation, it might

[1] THE LANCET, Sept. 5th, 1885.

Digitized by Google

do nothing but good by its sedative influence and power of checking secretion. Recollect, therefore, that the action of these drugs in glaucoma for good or ill is mainly mechanical, and that, apart from contraction or dilatation, the collateral result may prove the exact opposite of what you intended. Let us admit the correctness of the generally received views as to the causation or aggravation of glaucoma by excess of secretion or retention of fluids, owing to closure of the angle of the chamber and circumlental space by the expanded iris, and we can readily understand how the removal by operation of a portion of this both secretive and obstructive membrane may permanently relieve a condition which, unchecked, is certain to go on to destruction of the eye; and this is precisely what happens when a portion is excised, as in von Graefe's operation. Graefe had been struck, while attending the clinique of the elder Desmarres, with the remarkable results obtained by paracentesis in various affections of the eye. Mackenzie had pointed out that in glaucoma the globe became hard; it was clearly softened momentarily by tapping, and the larger the incision the better the result. Unfortunately—I should say fortunately in this case—when the wound was large the iris protruded, and to get rid of this difficulty von Graefe cut it off. (See Fig. 1.)[2]

FIG. 1.

How simple it all seems, and yet what stupendous results! Let me endeavour to bring home to you the vast benefits he has thus conferred upon suffering humanity. Sixteen years ago I was called by the late Dr. Watchorn to see a lady who had been struck with blindness some days before—in fact, both her eyes were in much the same condition as that of the poor woman with the green pupil you have just examined. She had bare perception of light with the left eye, was in an agony of pain, and the right, by reason of the longer duration of the malady, was, so far as sight was concerned, beyond the reach of art. A large iridectomy upwards, however, instantly, as if by enchantment, stopped the whole process in both eyes, and from that day to this she has with the left eye enjoyed most excellent vision, both for near and distant objects. We do not succeed like that in every case, but we do in a large proportion; and it is no exaggeration to say that hundreds of persons are every year saved from blindness by the performance of this simple operation. The one drawback to iridectomy is the mutilation of the pupil and consequent deformity with dazzling from circles of diffusion, and in order to avoid this ophthalmic surgeons have ever since 1856, the date of von Graefe's discovery, been endeavouring to improve upon the operation. Speaking on this subject, De Wecker says: "I am convinced that with the progress of knowledge some other proceeding more simple and essentially more logical will be substituted."[3] It may be so, but I am not of that opinion, nor can I recommend you to atempt any other operation in fulminating, acute, or inflammatory glaucoma. In certain specific and in some milder cases, it is true that less severe measures have sufficed, or must perforce be substituted. Sclerotomy, for instance, may take the place of iridectomy in the very incipent or doubtful stages of all forms of the disease; in hydrophthalmos, which is the glaucoma of children, where excision of the iris is so apt to be followed by rupture of the zonule, hæmorrhage, escape of vitreous, and collapse of the globe; and it must also take the place of iridectomy in adults suffering from the hæmorrhagic form of the disease, where the too sudden reduction of tension by iridectomy is apt to be followed by similar accidents. It should also be adopted in glaucoma absolutum, where it is impossible to excise the iris; and in cases of long-standing simple glaucoma, where advancing blindness is on the eve of invading the macula or point of fixation, and where any coarse operation may precipitate the impending catastrophe. Some ophthalmic surgeons (Schweigger, Wecker) even prefer sclerotomy in inflammatory cases, providing only extreme contraction of the pupil can be previously obtained by eserine, and it is undoubtedly useful as a preliminary to iridectomy when the inherent difficulties of the latter operation may be to some extent removed by a previous reduction of tension. In performing sclerotomy, the knife should enter and emerge in the corneo-sclerotic junction, precisely as if you were going to make a flap of four millimetres; pushed upward with a to-and-fro movement, and then slowly withdrawn, leaving about a fourth undivided.[4] (See Figs. 2 and 3.) But little after-treatment is needed, and although the chamber is not re-formed for some days, the patient may return home on the third. I have even in some cases, and for special reasons, discharged them at once. The great advantages of this operation are, that it may be repeated again and again, that it involves no muti-

FIG. 2. FIG. 3.

lation, and may be adopted as a supplementary procedure both before and after iridectomy.

Here is a patient, aged twenty-seven, from Ruddington, who illustrates the great advantages of these combined operations. She consulted me four years ago on account of excessively painful glaucoma consummatum of the left eye, the result of extensive iritic adhesions. As she was young and good-looking I did not like to extirpate the eyeball, and therefore divided the optic and ciliary nerves, with complete relief to all her painful symptoms. A year ago, that is three years after the neurotomy, she applied again with intense iritis of the right eye, and as I feared that there might have been some re-formation of nerve tissue and consequent sympathetic mischief, I removed the left globe.[5] Nevertheless, the right eye speedily developed glaucoma, and I found it necessary to remove the upper segment of the iris. A few weeks later, however, the symptoms returned, and I excised the lower segment, again arresting the progress of the disease. Subsequently, in consequence of recurring attacks of blindness with excessive tension, I found it necessary twice to perform sclerotomy, with the result, as you see, of perfect restoration to sight, which remains and bids fair to remain.

In attempting sclerotomy or iridectomy, it sometimes happens, owing to the extreme narrowness of the anterior chamber, that the point of the knife gets entangled in the iris, and before it can be pushed across the chamber the aqueous escapes. When this is the case it is prudent to delay the operation, or limit it *pro tem.* to a paracentesis, and I have occasionally with advantage kept the wound patent, and let out the aqueous from time to time by the daily or more frequent use of a blunt probe, or, what is better, a Weber's caniliculus knife; indeed, some surgeons have lauded paracentesis as superior in certain cases to other operations. For instance, Dr. Cuignet, Ancien Médecin Principal à Lille, records a case of glaucoma cured after seventeen evacuations of the aqueous humour, and thus expresses himself respecting the operation: "C'est à tort qu'on a laissé l'iridectomié supplanter presque complete-ment la paracentèse cornéene, dans une foule de cas où celle ci était usitée jadis et jouit, en effet d'une réelle efficacité."[6] As an operation *per se*, however, if we must be limited to tapping, the vitreous chamber appears to me to offer much greater chances of success to the surgeon—an operation which has been strongly recommended by various authors, even so long as a hundred years ago (Guérin de Lyon); again in 1830 by Mackenzie and Middlemore; since then by the elder Desmarres; and most recently by Dr. G. L. Johnson,[7] who thus writes with reference to chronic and old-standing glaucoma: "With the light which modern research has shed upon the subject, it appears to me that it is useless to seek for improvement by attacking the angle of the anterior chamber (by sclerotomy or iridectomy), since the destructive processes are in that region already too far advanced, while the relief afforded is insignificant when compared to the gravity of the operation." In performing paracentesis of the vitreous, you must turn the eye inwards as much as possible, and then thrust a Wenzel's or Beer's cataract knife to the depth of about half

[2] The incision must be made in the corneo-sclerotic junction, and the upper quadrant of the iris removed right up to its ciliary border, taking care that no portion is trapped in the angles of the woun

[3] Therapeutique Oculaire, p. 320

[4] Sclerotomy does not act, as has been supposed, by the production of a permeable scar, but probably by establishing a new path by which fluid can reach the corneal and scleral lymph-spaces from the retraction of the cut membrane of Descemet (the posterior elastic lamina of the cornea).—*Brailey.*

an inch into the globe, withdraw the knife slowly, and bandage the eye with cotton wool. (See Fig. 4.)

Dr. Johnson says "the relief is always immediate and generally permanent"—a statement the latter part of which, I regret to say, I cannot endorse; for I have found that when the wound heals the patient is in much the same position as before;[8] although it is true that wounds of the sclerotic, owing to the constant movement of the ocular muscles, seldom heal firmly by the first intention; and it is well, as Dr. Dianoux has pointed out, to assist this disposition to gape by systematic massage as well as by a cross incision. Dr. Argyll Robertson taps the vitreous with a trephine, removing a small disc of sclerotic, an operation which appears to have been attended by considerable reaction (Brailey); and other surgeons, looking upon glaucoma as a spasm of the ciliary muscle, have endeavoured to relieve tension by dividing that muscle. Mr. Hancock, for instance, says: "I always looked upon glaucoma as caused by obstruction of the circulation, a strangling of the bloodvessels caused by spasmodic contraction of the ciliary muscle, analogous to the spasm so often observed in the muscular fibres of the urethra, as well as in the sphincter ani, in certain affections of those parts." In order to relieve this condition, he says: "I introduced a Beer's cataract knife at the outer and lower margin of the cornea where it joins the sclerotic; the point of the knife is then pushed obliquely backwards and downwards until the fibres of the sclerotic are divided obliquely for rather more than one-eighth of an inch; by this incision the ciliary muscle is divided, whilst the accumulated fluid flows by the edge of the knife,"[9]; Mr. Solomon has devised a similar method, which he terms "intra-ocular myotomy." This is effected "by entering a Beer's cataract knife at the corneo-sclerotic union, and then

FIG. 4.

pushing it through the pillars of the iris into the muscle, the flat surfaces of the blade being opposed on the one side to the sclerotic, and on the other to the rim of the lens. The anterior chamber is generally penetrated, and the posterior put in communication with the wound."[10] The late Mr. Nunneley used to practise a similar operation which went by his name; and quite recently Mr. George E. Walker of Liverpool has recommended a like procedure, which he terms "hypo-scleral cyclotomy." Mr. Walker contends that excessive use of the ciliary muscle is the cause of glaucoma, whether acute, subacute, or chronic; and adds, what is wanted to cure acute glaucoma is rest, perfect and profound, and this, he maintains, can be obtained in no way comparable to that of cyclotomy. He thus describes his operation: "Fix the eye by holding the conjunctiva with toothed forceps; with the narrowest knife possible pierce the cornea at a point opposite to that of fixation, about a line from the sclero-corneal junction; as soon as the point enters the anterior chamber, alter the direction of the knife so as to clear the edge of the lens, thrusting it through the iris for about a line, then, drawing back the knife, cut the tissues up to the sclerotic.[11] The results attained in these cases, when favourable, must have been greatly due to the evacuation of intra-ocular fluids, since post-mortem examinations have demonstrated that the muscle is rarely divided, as Wecker has remarked:—"Les expériences faites sur le cadavre, après avoir exécuté l'opération, prouvent qu'on ne réussit à couper qu'une partie des fibres circulaires et radiées du muscle ciliare, aussi l'opération, n'agit elle qu'à la manière des paracentèses, et c'est ainsi qu'elle peut véritablement être salutaire."[12]

Donders always maintained that glaucoma was caused by irritation of the fifth pair of nerves, and the intimate connexion of the attacks with derangements of the trigeminal and sympathetic nervous system is so marked that one can only wonder that the disease has not been attacked more frequently on that side. I have endeavoured to contribute my quota to this end by galvanising the sympathetic, and Badal proposes to alleviate the symptoms by tearing out the nasal branches of the fifth,[13] an operation spoken of in the highest terms by Lagrange, who, from an experience of eighty-one cases, declares that in glaucoma the pain disappears, tension decreases, and vision improves, even when both sclerotomy and iridectomy have failed to afford relief.[14] I have been asked whether I consider glaucoma as essentially an inflammatory disease. Well, I should say not. I look upon inflammation as an accident of glaucoma—a something superadded; and the simple form where there is no inflammation, and, what is more remarkable, often but slight tension—the old amaurosis with excavation of the optic disc,—as the real type of the disease. It is true that the greatest variety of opinions prevails upon this subject. Von Graefe, for instance, always thought that glaucoma was a serious choroiditis, pure and simple, an opinion apparently shared by Mauthner. Donders, v. Hippel, and Grünhagen hold that the hyper-secretion is caused by irritation of the fifth pair of nerves. Max Knies and Adolph Weber contend that the disease is merely one of retention, Weber believing that it is the swelling of the ciliary processes which blocks the angle of the chamber, and Brailey to a certain extent appears to adopt this view; while Priestley Smith insists that the closing up of the circumlental space is simply due to the increased size of the lens, which, he has shown, is a natural phenomenon of life which goes hand in hand with advancing years. However that may be, it is certain that glaucoma very seldom occurs under fifty years of age, and that women who suffer from climacteric congestions are the most frequent victims, whilst the class of persons most commonly afflicted are those who are naturally weak or poorly fed, who have had troubles, who have used the eyes inordinately for near objects, or whose occupation has necessitated much stooping, and consequent extra- and intra-ocular congestion. The disease is symmetrical, both eyes being affected, though I have known fifteen years to elapse before the second was attacked. The smaller the eye the greater the chance of its becoming glaucomatous, rigidity of the sclerotic being most manifest in hypermetropes—a condition you may sometimes diagnose by a full hard pulse, such as we remarked in the male patient suffering from simple glaucoma. Irregularities of the circulation, such as climacteric flushings, often precede the attacks, and patients are not unfrequently found to be suffering from atheroma, sclerosis, or hyaloid degeneration of the arteries. Whatever reduces tone and relaxes the muscular system is provocative of the disease. "Lorsque je me sens brisé de fatigue, je suis certain de voir mes arcs en ciel," is a remark recently made by one of Wecker's clinique, which contains a lesson for us all. *Per contra*, whatever braces the system, increases the muscular tone, contracts the pupils, and ensures profound sleep (when, I need hardly remind you, the pupils are normally contracted) will tend to dissipate the prodomata of an attack.

From all this it is evident that those who are threatened with glaucoma should observe certain precautions. They should retire early, avoid stimulants and excesses of all kinds, insist upon regular action of the bowels, have glasses

[8] I prefer, myself, to let out the vitreous through the pupil after removal of the lens, an operation which yields marvellous results in cases of advanced glaucoma.

[13] The nasal nerve which we are told to divide in Badal's operation is a branch of the ophthalmic division of the fifth, and gives off a filament to the lenticular ganglion, two or three ciliary direct to the eyeball, and at the inner side a considerable branch, the infra-trochlear, which leaves the orbit at its fore part, and is really the nerve which is torn in Badal's operation. Its position is indicated by a line drawn through the centre of the nail when the finger is placed close to the supra-orbital ridge, its tip resting on the side of the nose, or by a line drawn from the angle of the mouth to the inner canthus. The nerve, which lies very deeply, is best got at by cutting down to the bone on each side of it, and then tearing it up by the roots with a strabismus hook. The effect of the operation is supposed to be due to the disruption of the sensory root of the ciliary ganglion, or to an ascending neuritis of the torn nerve extending to the ganglion. Badal's idea was to relieve pain by stretching the nerve. He found, however, as a matter of experience, that tension of the eyeball was also notably reduced. Lagrange considers the operation one of the best in ophthalmic surgery.

accurately adapted, use the eyes for near objects as little as possible, get out of doors, and never read or work when lying down, leaning forward, or travelling in a railway carriage. They should also cultivate excitement of a healthy and pleasurable nature, and friends should be instructed to protect them as far as possible from anxiety, worry, contradiction, and those moral emotions of a depressing character, which the cases I have quoted at the commencement of this lecture show us so frequently precede an attack. Thirty years ago the elder Desmarres wrote: "As glaucoma is incurable, it is difficult to suggest any treatment." Now, owing to the labours of von Graefe, we are able to deal successfully with the great majority of acute cases, one-half being restored to excellent sight, and the progress of the disease, as a rule, arrested in the remainder. This remark, however, does not apply to cases of simple glaucoma, for although the *status quo* may be maintained by treatment in a large proportion, and some slightly improved, still we cannot say that we have any cure for the disease, and 20 per cent. are apparently worse for operative interference. What is to be done with these cases? Gentlemen, that is "le grand problème"—the task before us. Von Graefe has conferred a boon, but it appears to me that he has also entailed an obligation; and that it behoves us, in emulation of the great master, not only to work out a rational treatment for cases of simple glaucoma, but also so far to extend a knowledge of our art as to bring within the range of science those numerous and distressing cases of acute glaucoma which are mistaken for other diseases, incorrectly diagnosed, or lost for want of treatment by qualified and experienced practitioners.

NOTES ON THE

TREATMENT OF SOME OF THE FORMS OF DISEASE INVOLVING THE AORTIC VALVES.

BY ARTHUR ERNEST SANSOM, M.D. LOND., F.R.C.P.,
PHYSICIAN TO THE LONDON HOSPITAL; CONSULTING PHYSICIAN TO THE NORTH-EASTERN HOSPITAL FOR CHILDREN; HONORARY FELLOW OF KING'S COLLEGE, LONDON.

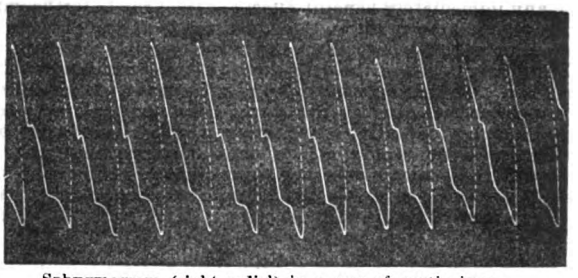
THE purpose of this communication is to consider the evidence afforded by the observation and investigation of actual cases concerning the problems of the treatment of diseased conditions of the aortic outlet. The plan adopted is what I may call the clinical method. No one can estimate more highly than myself the value of that which I may call by way of distinction the scientific method, by which I mean the investigation, by all means of precision available, of the mode of action of a given remedy. The conditions, however, presented by patients who apply to us for treatment are so varied and so varying that even when a medicinal agent has been investigated with rigid scientific accuracy, its practical value can only be tested by the experience afforded by a large number of cases. The scientific method helps us enormously, but for practical purposes it is the clinical method on which in practical therapeutics we must chiefly rely. I have already adopted this plan of observation in the case of some forms of disease affecting the mitral orifice. Perhaps the chief problem presented by these was the selection of agents which, acting as tonics to the heart, should restore and maintain compensation. I considered the action to this end especially of digitalis, caffeine, and convallaria. I concluded that digitalis was especially valuable in mitral regurgitation, with caffeine to supplant it or to enhance its action at intervals, especially when dropsy was a marked symptom; but that convallaria was more efficient for general and protracted administration when necessary in cases of mitral stenosis. I commend this question to the further investigation of practical physicians.

Now I come to consider the treatment of diseased conditions of the aortic outlet. I do not include aneurysm of the aorta nor any external conditions which may affect the vessel. I am obliged to say *in limine* that the difficulties of investigation are much greater than in mitral diseases—the conditions, especially in reference to treatment, are more complex. It is of the first importance to group [illegible] cases. I shall do this from the clinical standpoint, appe[illegible] only to the evidence of morbid anatomy when such is necessary for the elucidation of the therapeutic problems. The classification of the forms of aortic disease which I propose is (1) Rheumatic, (2) Atheromatous, (3) Traumatic, and (4) Septic or Ulcerative. Of these classes the first two comprise the largest number of cases, so that in most instances the first question which presents itself is whether a patient manifesting the physical signs of aortic obstruction or regurgitation shall be placed in the *rheumatic* or the *atheromatous* division. Of ninety-four private patients observed by myself, twenty-nine were rheumatic (30 per cent.). By this I mean that they presented evidence of disease of the aortic orifice originating in rheumatic endocarditis. In fifty necropsies in cases of hospital patients the aortic valves were thickened in twenty-five, atheromatous in eighteen, and presented vegetations in twenty-two; the changes were directly traceable to rheumatic endocarditis in twenty-two cases, and to atheroma in twenty-one. From all the evidence, therefore, I think we may conclude, if we take our observations from patients of all ages, that the *primâ-facie* chances whether the diseased conditions proceed from rheumatism or from the endarteritis which proceeds to atheroma are about equal. It is clear, however, that rheumatic endocarditis is especially a disease of early life, whilst atheroma is an affection of the later periods, though it is possible for valves which have been altered from rheumatism to undergo atheromatous changes at almost any age. Rheumatic endocarditis may involve the aortic valves in very young children, though it is in early adult life that the disease most frequently attacks them. In 173 cases of all forms of cardiac disease affecting children under twelve years of age I have found the aortic orifice involved in sixteen, of which fourteen were associated with acute or subacute rheumatism or slighter forms of articular pain, whilst in two cases the affection appeared to me to be in definite relation with measles. In these cases of children, eight presented evidence of obstruction at the aortic outlet, and eight manifested aortic regurgitation. Eight of these cases were accompanied by mitral regurgitation; two were double aortic. The tendency to the implication of the mitral was to that of the aortic as nearly five to one (72:15). It is perhaps of practical importance to note that the aortic valves were involved in just as great degree when there were but slight articular phenomena, as when there was the more pronounced and typical rheumatic fever.

I think we may divide, for practical purposes of therapeutics, those patients who consult us for aortic valvular disease which we consider to be distinctly referable to rheumatism into two categories. In the one there are no symptoms referred to the heart and circulation; in the other there *are* such symptoms. It is not very uncommon for a lad or young man to come to us for an affection in no direct way suggesting disturbance of the organs of circulation, and yet for there to be manifest disease at the aortic outlet, obstructive, regurgitant, or both combined. For instance, I have been consulted by a young man of seventeen for incontinence of urine, without the slightest complaint of any symptom to be referred to disorder of circulation or respiration, and yet I have found a loud diastolic murmur of aortic regurgitation, with the heaving impulse of a considerably hypertrophied left ventricle. In the case of a young person, even though there be no history of anterior rheumatism, it is almost safe to conclude that any change, whether of obstruction or regurgitation, at the aortic orifice is due to a rheumatic endocarditis, past or present.

In such cases as that just mentioned there has been, in all probability, a slowly progressing endocarditis, with thickening and retraction of the aortic cusps, the left ventricle gradually becoming hypertrophied and adapted to the new conditions, which have ultimately become quiescent and stationary, so that compensation is perfect. In such a case, I think we may say with confidence that all forms of heart tonics, all drugs whose action it is to enhance the force of ventricular systole, are positively hurtful. It may be well at some periods to regulate the digestive powers, and perhaps to administer such general tonics as iron, strychnia, or arsenic, but any agent which alters the rhythm of the heart should be withheld. The danger in these cases is a new manifestation of the rheumatic process, with attendant endocarditis, and the

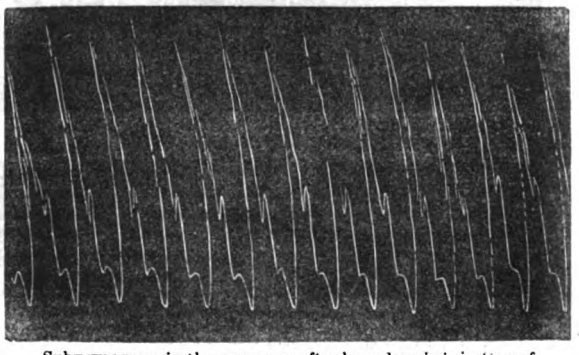
Digitized by Google



importance of preventive measures *quâ* rheumatism should be indicated.

In the greater proportion of our cases, however, of aortic valvular disease of rheumatic origin, there are symptoms which we can refer to some error of compensation—some want of adaptation to the altered physical conditions. We may ask what these signs are. In a large majority of the cases of aortic disease caused by rheumatic endocarditis, the mitral valve is also involved; there is most commonly an accompanying mitral regurgitation, but in some there is no evidence of anything except the aortic lesion. We may inquire whether these differ in their signs and symptoms from those in which the mitral lesion is manifest. I think we may conclude that in the most common cases of mitral regurgitation the failure of the heart power is manifested by a fairly definite train of symptoms—dyspnœa occurring as an early symptom and increasing in severity as time goes on, œdema appearing and gradually advancing,—but pain at heart, in my experience, though it may exist, is not a very marked and notable, and not a very early symptom. On the other hand, I have found that in the rheumatic cases in which the aortic orifice is involved, whilst there is no evidence of structural imperfection of the mitral, pain and distress directly referred to the heart are marked and notable symptoms. This pain, in some cases, graduates through many stages to a nearly constant condition of extreme distress; in others it is variable, occurring as a spasm, associated in some cases with faintness, in others with palpitation, and in rare cases presenting the character of angina. It is considered by many that signs of angina are more frequent in cases of aortic disease associated with atheroma, but I have seen some cases in distinct relation with the rheumatic forms of aortic disease. For instance, in a lady aged thirty-one, in whom the signs were those of aortic stenosis in all probability of rheumatic causation, there was the manifestation of true angina pectoris. In another case, a man aged twenty-one, long under observation with aortic obstruction and regurgitation, mitral regurgitation, and tricuspid regurgitation, after the manifestation of signs of deep distress at intervals during two years, began to exhibit signs of defined angina with intense agony. In another case a man of twenty-five, admitted into hospital with acute rheumatism, attended with signs of aortic obstruction and incompetency with mitral regurgitation, there developed whilst in hospital attacks of true angina, which were promptly arrested by the inhalation of nitrite of amyl.

It is in the rheumatic rather than the atheromatous forms that we find examples of very free regurgitation. It would seem that in many cases the fibrous change following the exudation and cellular infiltration of rheumatic endocarditis in the valve and its neighbourhood is brought about too rapidly for compensatory hypertrophy to occur *pari passu*. It is scarcely important, I think, to debate whether in case of such imperfection of the valve hypertrophy of the ventricle precedes dilatation or *vice versâ*. It appears to me most probable that this is a question of nutrition—if the nutritive needs of the ventricle are adequately supplied so that the increased intra-ventricular pressure can be antagonised, then hypertrophy, if not, then dilatation. In a large proportion of the cases, when the storm of endocarditis which has induced disease at the aortic outlet has apparently subsided, there are some signs of trouble as regards the heart or circulation. Probably our first impulse is to aid the ventricles by administering digitalis or some other cardiac tonic. Observers seem to be much divided on the question whether or not it is advisable to administer digitalis in cases manifesting aortic regurgitation. On this point I have the following observations to offer:—



1. It has appeared to me that in some cases of aortic disease associated with rheumatism digitalis has positively increased the distresses and the dangers of the patient. For instance, in a case manifesting a systolic and diastolic murmur at the base, with systolic murmur at the apex and signs of considerable cardiac hypertrophy, but evidence of ill compensation afforded by the gradual on-come of œdema and dyspnœa, the temperature being then slightly subnormal, four minims (only) of tincture of digitalis were given in the ordinary diuretic mixture three times a day. The following day there were frequent attacks of urgent orthopnœa, intense anxiety, sweating, and pain at the heart of the character of angina. I was so convinced that in this case digitalis was likely to act as "the opium of the heart" and to allay the symptoms, that I tried the subcutaneous injection of one-fiftieth of a grain of digitaline. I soon found that the drug aggravated the distress; improvement followed the administration of five-minim doses of tincture of aconite and the occasional inhalation of nitrite of amyl (see Figs. 1, 2, 3, and 4). In another case, in which there were signs, in addition to those in the former case, of tricuspid regurgitation, no digitalis, but five-minim doses of tincture of aconite were ordered. The pulse-rate was then 140. Three doses were given during the night, and then it fell to 132, afterwards to 128, and in the morning it was 88 and the patient much relieved.

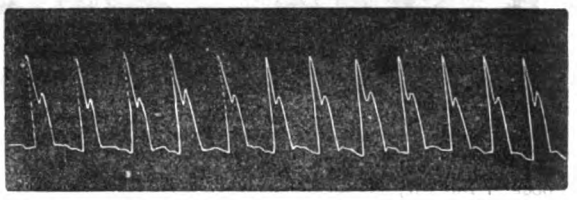
FIG. 3.



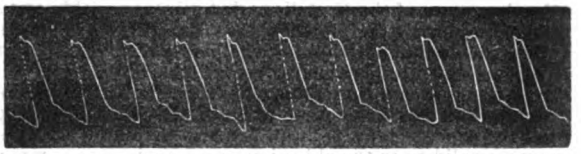


FIG. 4.

Sphygmograms after treatment by five-minim doses of tincture of aconite and occasional inhalations of amyl nitrite.

I may here mention a third case, that of a female aged thirty-eight, manifesting aortic obstruction and insufficiency and mitral regurgitation, with hypertrophy and dilatation of the heart, in whom the subsidence of all cardiac distress, and probably the establishment of good compensation, were brought about without the administration of any agent having a special action upon the heart, whether tonic or sedative. In the case I mention, rest in bed for four weeks, with an occasional purgative, and sometimes the administration of a draught of sulphuric ether, ammonia,

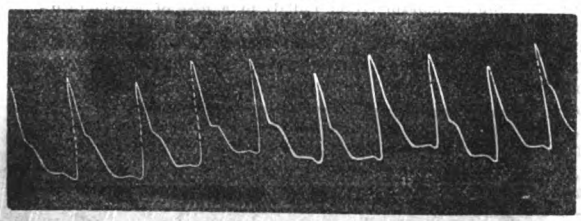
Digitized by Google

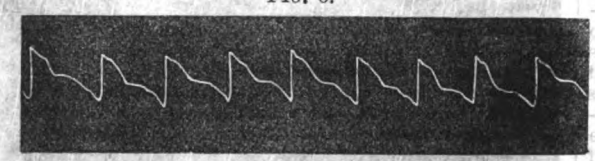
and compound tincture of camphor, were the only therapeutic means adopted. (See Figs. 5 and 6.)

2. A second objection which may be urged against digitalis in rheumatic aortic disease, from the experience of my cases, is that in a few instances, though there may be no manifestly adverse signs to its employment from its action on the heart, it nevertheless causes sickness, and the patient is intolerant of it. In the case of a boy of twelve, in whom this occurred, convallaria was substituted, and the boy manifested great improvement in all ways. (See Fig. 7.)

3. A third objection which may be brought as an indictment against digitalis—and the validity of this may not be so susceptible of direct proof—is that, though no evidence of any immediately baneful effects of the drug is forthcoming, death has occurred in such manner as to give rise to the opinion that there may be some relation between the administration of the drug and the fatal termination of the case. I was led to think this possible many years ago, when a patient of mine at the Royal Chest Hospital, City-road, London, with aortic regurgitation, who had greatly improved under a course of digitalis whilst an in-patient, and was permitted to continue the course as an out-patient, died suddenly in the street. Of course it is acknowledged that in this form of cardiac disease sudden death not unfrequently

FIG. 5.





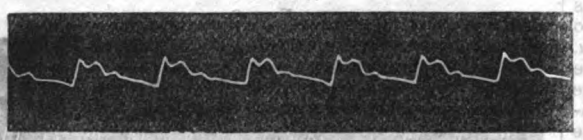


FIG. 6.

occurs. But why should this be when there are manifest signs of improvement? I think the physiological action of digitalis affords a sufficient explanation. The slowing of the heart, the elongation of the diastolic period, salutary within certain limits, becomes baneful when these limits are overstepped. Then the individual through the imperfectly closed aortic orifice bleeds into his own left ventricle; and if he happen to be in the erect position the encephalon suffers in the greatest degree from this abstraction of blood. Thus ensues syncope, and the syncope may be fatal. My own opinion is that there is some validity to the objection urged against the employment of digitalis in aortic regurgitation when such regurgitation is considerable, even though there may be for a long period signs of improvement under its use. I think the proposition should be strongly enforced that it is undesirable for a patient with aortic regurgitation, when such exists in considerable degree, to continue to take digitalis without medical supervision for long periods. The course that is legitimate enough in cases of mitral regurgitation is to be deprecated in those of aortic regurgitation.

From the foregoing considerations, therefore, I must conclude that in certain cases of the affection we are now considering digitalis is positively hurtful. We may next inquire whether any other agents having a tonic effect upon the heart fibre may be with advantage substituted for it. I have already quoted an instance in which convallaria advantageously replaced digitalis; in others temporary relief has followed the administration of caffeine. I do not propose to consider the evidence concerning strophanthus, which may prove valuable, because I consider my data as insufficient. I shall further consider the effects of caffeine and convallaria when we come to consider the cases of aortic disease caused by atheroma.

It is appropriate now to turn our attention to a section of the rheumatic cases in which, though no adverse signs as regards the action of the special cardiac tonics employed have been manifested, all has appeared unavailing, and there has been a steady advance of the cardiac trouble without any evidence of good results from *any* of the agents employed. This has happened in a few instances, and it behoves us to investigate the cause. I will mention a case in illustration. Miss A——, aged twenty-two, with a history of subacute rheumatism, manifested loud systolic murmurs at base and apex. There was marked anæmia. Digitalis, in the form of the tincture first and the powdered leaves subsequently, together with iron, were administered carefully and regularly for five weeks. There was no improvement. The tension of the pulse continued extremely low; there was no pyrexia, but simply a general enfeeblement. Then twenty-minim doses of the tincture of convallaria majalis were tried for a fortnight, but there was no response. A suspension of the cardiac remedies, with the administration alone of iron and nux vomica and other general tonics, proved equally unavailing. Subsequently caffeine was found powerless over the failing ventricle, and, in spite of the most tender nursing and care, death took place in the course of about twelve weeks from the first observation. It is probable that other physicians have had similar painful experiences with this. To what can we attribute the absolute failure of cardiac tonics in such a case? It seems to me most probable that there is in some cases initiated by rheumatism a very protracted course of endocarditis, and that with this the cardiac muscle is impaired, for I am convinced that in the path of the endocardial inflammation there is a widely spread involvement of the muscular fibrillæ and the surrounding structures, which are infiltrated with cellular elements. The muscle cannot respond to the influence which under normal conditions stimulates its energy of contraction. Of course the question occurs, in a similar case what can we do? The first portion of the answer to this question is, I think, to treat with rest and care the slight manifestations of the anterior rheumatism. In a young subject manifesting some pyrexia with pains in the joints, even though these be very slightly marked, anæmia, and especially quick pulse with irritability of heart, one should enforce the importance of rest. I cannot resist the conclusion that the treatment by salicin or the salicylates, which so wide an experience demonstrates to contribute to the comfort of the patient in acute rheumatism, tends also to manifest a favourable influence on the cardiac complications. It is true that we have no direct statistical evidence of the value of the treatment as regards endocarditis; for the ratio of heart complications appears to be about the same in those treated by other methods, but it is probable that at the time of the available statistics the treatment had not been commenced sufficiently early, and probably the slight manifestations in the young had not been treated at all. I have been very careful in this paper, hitherto, to keep closely to the strictly legitimate conclusions from observed facts, but I may hazard the opinion, not perhaps to be substantiated by positive evidence, that the forms of cardiac disease as observed now in patients treated by the salicylates are not so extensive and severe as they were formerly, when patients were not so treated. I have distinct and indisputable evidence that in some cases manifesting aortic disease, though no articular phenomena were in existence, the administration of the salicylates in full doses has been followed by a marked amelioration of the symptoms referable to the heart. I may be permitted to formulate my conclusions as to the treatment of disease of the aortic valves resulting from rheumatic endocarditis:—

1. In all cases manifesting signs of disease at the aortic orifice, whether obstructive or regurgitant, if there be an immediate association with acute or subacute rheumatism, it is of the first importance to counsel complete rest in bed. The observance of such rest is sometimes sufficient to allow a complete compensation to be brought about.

Digitized by Google

2. In such cases digitalis and other special cardiac tonics should not, as a rule, be employed until time has been given for observation, and for the use of appropriate means to subserve general nutrition.

3. In cases in which there is reason to believe that the lesion is chronic, in relation with a remote attack of rheumatic fever, with no evidence of the recent existence of subacute rheumatism, the administration of digitalis, convallaria, or caffeine is indicated, but a prolonged course of any or either of these agents is undesirable. It is better that they be administered for periods of one or two weeks, and then that general tonics be alone prescribed; for, the energy of the ventricles being once increased, this may be maintained without the aid of agents specially influencing the cardiac muscular fibre; and in aortic disease agents which considerably modify the rhythm of the heart are not without danger.

4. In the case of a young subject in whom there is no evident manifestation of rheumatism, and yet a very low tension of pulse, which cardiac tonics fail to modify, it is probable that rheumatic endocarditis is in progress, and absolute rest with the administration of the salicylates should be counselled. *(To be continued.)*

CASE ILLUSTRATING THE

ADVANTAGES AND RISKS OF PURGATION DURING CONVALESCENCE FROM ABDOMINAL SECTION.

BY JOHN D. MALCOLM, M.B., C.M., F.R.C.S. ED.,
ASSISTANT SURGEON, SAMARITAN FREE HOSPITAL.

LAST September Sir Spencer Wells removed a large ovarian tumour from a patient fifty-seven years of age, and he has kindly permitted me to publish the following notes of the case.

The pedicle of the tumour was very broad, and had to be secured in several pieces by stout silk ligatures; but otherwise the operation was a simple one. After operation the patient complained of much abdominal pain, and a drachm and a half of tincture of opium was administered by the bowel in the first twelve hours. The pain continued, and a drachm and a half of laudanum, gradually reduced to a drachm, in the twenty-four hours, was given for the next four days, after which the administration of laudanum was discontinued. After the operation the temperature of the patient gradually rose, and at 9.30 P.M. on the following day it was 101·4° F. in the axilla; it then gradually, but not very steadily, fell till the fifth day, when it was as low as 98·6°.

Sir Spencer Wells went abroad on the third day after the operation, leaving me in charge of the case. On the evening of the third day, and all through the fourth day, there was a tendency to sickness and abdominal distension, but flatus passed freely from the rectum. On the fifth day that portion of the bowel was found to contain fæces, and a small enema produced a copious evacuation, after which the feeling of sickness and the distension passed off. The action of the bowels was followed by considerable pain in the right groin about the position of the pedicle, and the temperature rose in a few hours to 100° in the axilla, but again gradually fell to 98° on the seventh day after operation. The bowels moved seven times between the fifth and tenth days, and much flatus also escaped. During this time, however, the pain in the right groin increased, until the patient could not bear the slightest pressure over this part. The rest of the abdomen became slightly distended, but was free from tenderness. The administration of one-sixtieth of a grain of atropia and one-twelfth of a grain of muriate of morphia, repeated every four hours, eased the pain; but the appetite became very bad, and the patient felt constantly sick after the eighth day. She also lost strength, and her pulse, which had been down to 84 and of good character, gradually rose to 100, and became very feeble. On the tenth day her temperature, which had not been above 98·6° for two days, also began to rise a little, and reached 99·6° in the axilla at 9.30 A.M.; she had been very restless all night, could not take any food, and felt very sick, while the abdomen had become more distended. This grouping of symptoms after abdominal section I have learned to associate with obstruction in the bowels, which may lead to a rapidly fatal termination of the case. In the belief therefore that my patient was in extreme danger from this cause, and that the best method of treatment of this condition at this stage is by the administration of a purgative, I gave her a pill containing one-third of a grain of calomel and as much jalap, one grain of compound extract of colocynth, one grain of extract of aloes, one-twentieth of a grain of jalapine, and a little ginger. The patient had frequently used similar pills, prescribed by her own medical attendant, Dr. Morley of Blackburn, and they had moved the bowels gently during health. On this occasion the pill produced two small loose motions, and a dose of Hunyadi water, given next morning, was followed by other loose motions. The last of these was at 5 P.M. on the eleventh day after operation. Twelve hours after the pill was given the temperature had risen to 100·6° in the axilla, perspiration was extremely profuse, and the patient had become alarmingly weak, but she was then able to take food without feeling sick. After the bowels were quiet twenty minims of tincture of opium were given by the rectum, and the patient had a good night's rest. She was much stronger next morning, and this improvement continued. The pain in the right groin, however, became more severe, and the tenderness radiated over the abdomen to some distance from this part. The temperature continued feverish but irregular till the thirteenth day, when it fell to normal and remained so. On this day also the pain shifted upwards and towards the right loin, and next morning there was only slight tenderness on pressure in the groin and none in the loin. Now, however, the patient at once complained of pain when I applied pressure over the colon in the region of the gall bladder. The seat of tenderness afterwards shifted from time to time along the course of the colon, and finally was found low down in the left groin on the fifteenth day after the operation. The bowels had then been quiet for four days, and I warned the patient that she would probably soon have an action of the bowels with considerable pain. That afternoon several large, very hard fæcal masses passed into the rectum, whence they were removed with some difficulty by the nurse, after which recovery was uninterrupted.

This case is very instructive in connexion with the question of the administration of purgatives during convalescence from operations for abdominal tumour. It is evident that the masses of fæces which were removed on the fifteenth day after operation were the cause of all the difficulty and danger in this case, by producing a partial obstruction in the bowel. The fæcal accumulation had been impacted in or near the cæcum, and the efforts of the bowel were insufficient to remove it, probably on account of the condition of paresis of the intestines which I have shown follows abdominal section, and is "an important factor in the production of obstruction of the bowels in these cases."[1] When, however, the impacted mass was dislodged by the aid of the purgative medicine, the sickness and distension at once disappeared. At the same time the temperature of the patient rose distinctly, and this in spite of a most profuse perspiration; pain in the groin became more severe and diffuse, and the patient's strength failed alarmingly. It is evident, then, that in this case purgation relieved a partial obstruction in the bowel, but at the same time increased, or rather renewed, the inflammation in and around the pedicle. Many cases have taught me that this is the way in which purgation may be beneficial during peritonitis after abdominal section. Purgation during peritonitis may therefore be necessary and proper treatment, but it is inaccurate to say that the purgation cures the peritonitis. On the contrary, the fact must be recognised that the administration of a purgative in such cases is resorted to at the risk of increasing the severity of any inflammation implicating the wall of the gut; and in severe constipation, even when there has been no recent inflammation, a smart purge may produce a great deal of inflammatory action in and around peritoneal adhesions. Might not the explanation here given apply to the interesting case published by Mr. Frank Sturges in THE LANCET of Oct. 15th (p. 757)? As in cases of large abdominal tumour it may be very difficult or impossible to thoroughly clear the bowels, so, during pregnancy, constipation is not uncommon, and women, especially of the poorer classes, are often very careless in this respect. After Mr. Sturges' patient

[1] Vide abstract of paper read before the Royal Medical and Chirurgical Society, THE LANCET, Oct. 29th, p. 860.

Digitized by Google

took the pills under the circumstances he describes, she had "two actions of the bowels causing such intense pain that she twice fainted"; and, as in the case I have recorded, purgation was accompanied by rise of temperature and increase in the severity of the abdominal pain, while the patient became "so very ill that" Mr. Sturges "hardly thought she could recover"; but as soon as the bowel passage was made free the intestinal symptoms disappeared, and the patient steadily improved.

Bryanston-street, Portman-square, W.

A CONTRIBUTION TO THE

SURGICAL TREATMENT OF GALL-STONES.[1]

BY W. A. MACKAY, M.B., C.M.ED.

MARIA ALVAREZ G——, aged forty years, married, has had five children, of which two are still alive. She has been in the habit of suckling her children for twenty months each, but her last child she weaned at fifteen months of age. In her family history she knew no instance of jaundice or of malignant disease. But, from what I have since heard, it is probable that her father died of cancer of the stomach. In the beginning of March, 1886, the patient gave the following account of her illness. Eight months previously, while nursing her youngest child, she began to feel unwell and became very bloodless; she therefore weaned the child, and took as a tonic arsenic and iron. Still, her condition grew worse, and she began to suffer great pain in her back and chest; and about this time one of her friends remarked that her eyes were yellow. Then she took to bed. When fifteen days in bed she became jaundiced, but feeling somewhat better she began to go about again, although the pain and jaundice persisted. Last Christmas she felt a swelling in the situation of the gall bladder. Being somewhat alarmed, she drew the attention of a female friend to this region, but, to her surprise, the swelling had disappeared. The patient, seeking for an explanation of this phenomenon, soon found that the swelling was generally present at night but absent in the morning. During the three months before I saw her, menstruation, which till then had been normal, ceased to occur, being, in the patient's opinion, replaced by a flow of blood which took place from the gum near the last right lower molar on its outer aspect. The bleeding was painless, and made itself felt by flowing into the mouth. Very soon it ceased to flow and became a mere oozing. This oozing of blood from the gum lasted four or five days, as the patient's menstrual period had always done, and it occurred on each successive period during a term of four months. Afterwards fluid began to collect in the abdomen and had steadily increased.

On examination I found the patient deeply jaundiced, and suffering from great abdominal distension. I could with difficulty make out a rounded body where she had formerly observed the intermittent swelling. Examination of the chest revealed nothing abnormal. Since the patient came under observation the pulse had generally been over 100; the temperature normal; the urine free from albumen, but deeply bile-stained; the motions, generally two a day, formed and of a clayey-white colour, evidently without bile.

On March 27th I tapped the abdomen below the umbilicus and drew off 400 ounces of fluid, deeply bile-stained. The abdomen was now so flaccid that its anterior wall bulged slightly over the situation of the tumour, and a careful examination left little doubt that we had to deal with a distended gall bladder. The liver was slightly enlarged, and presented a smooth regular border. The patient was most anxious to have something done which would relieve her of pain, which was at times intense, and which she affirmed was worse after meals. Being of opinion that she suffered from impacted calculus, I determined to operate.

On March 28th the ascites had returned to such an extent that there was evidently no time to be lost. Therefore at 4 P.M. the following operation was performed in a large empty room of a private hospital. Transfixing a small fold of skin over the prominence of the tumour, along the external border of the right rectus muscle, about midway between the margin of the ribs and the umbilicus, I dissected down and exposed the peritoneum. On opening the cavity a considerable amount of ascitic bile-stained fluid escaped, and the base of the gall bladder presented itself in the wound. Here an assistant steadied it with a hook while I drew off its contents by means of a trocar. The gall bladder was distended to about the size of a large pear, and its contents seemed to consist of a sticky bile. Withdrawing the trocar, I enlarged the aperture in the fundus upwards where it seemed least vascular, and on inserting the little finger of my right hand I felt a calculus impacted in the cystic duct. With the index finger of the left hand in the abdominal cavity outside the gall bladder, acting against the little finger inside, I extracted the calculus without injury to the duct. After I had ascertained that there were no more gall-stones, the aperture in the gall bladder was secured to the lips of the abdominal incision by means of a continuous silk suture. The incision in the abdominal wall measured less than two inches, while the aperture in the fundus of the gall bladder was just enough to allow the exit of the stone. No vessel was met with which needed ligature, nor was there the smallest inconvenience from bleeding. The calculus weighed 2 grms. 60 centigrms., and was about the size of an olive. Antiseptic precautions consisted in previously boiling the needles and silk in a solution of carbolic acid. A slight dressing of absorbent cotton wool was fastened over the wound with plaster, and over all was placed a fine flannel binder. The patient rallied at once from the operation and expressed herself as feeling very well and free from pain. The anæsthetic employed was a mixture of chloroform and ether.

March 29th.—Wound dressed at 10 A.M.; temperature 99·8°; pulse 96; skin around wound deeply stained with bile, which flowed freely from the fistula, drenching the absorbent dressing and soaking through to the mattress. The patient was placed on milk diet with a little cornflour. She had passed two motions during the night, formed, but without bile. The wound healed rapidly by first intention.

With a view to ascertain the quantity of bile poured out, an abundant dressing of absorbent wool was weighed daily at 10 A.M., before putting it over the wound, and again on removal the following day at the same hour. The table annexed will show the quantity of bile excreted every twenty-four hours.

Date.	Quantity of bile in 24 hours.	No. of motions in 24 hours.	Temperature.		Pulse.

On April 1st ascites was again noticed, and the patient was much troubled by flatulence. She was ordered Hunyádi Janos water. After taking some cornflour and milk she vomited, and the vomit seemed to contain bile. On the 3rd it was noted that the ascites had almost disappeared, but flatulence distressed the patient. She took Hunyádi water again. On the 6th her motions contained traces of blood, which passed off on the 9th. Then her general condition improved considerably, and she was able to sit in her chair a few hours daily. At this time she took large quantities of milk, cornflour, custard, and beef-tea. She had no pain since the operation, and was very cheerful; but fluid was

[1] Read at the annual meeting of the British Medical Association at Brighton.

Digitized by Google

again accumulating in the abdomen. In this way she went on with, but little change, till the morning of April 23rd. On that morning the flow of bile ceased suddenly, so that the dressing removed on the morning of the 24th only contained a trace. The ascites had become so distressing that I tapped, drawing off on the afternoon of that day 294 ounces of a bile-stained fluid containing a considerable amount of blood. After this the record is that of a patient dying slowly, but without pain, of an incurable disease. On May 8th she died. The post-mortem examination revealed cancer of the pancreas and liver, especially the left lobe. The common bile duct was completely occluded, and perforation had occurred at its origin.

Remarks.—On reviewing the case, it appears to me that the tale of her illness as told by the patient is a history of biliary calculus. The intermittent character of the tumour she felt in her abdomen seemed rather to indicate calculus causing obstruction than stenosis of the duct from malignant disease; while the transitory jaundice referred to by her friend and the colicky pain shooting through to the back were alike characteristic of gall-stones. I expected to find a calculus causing obstruction of the common duct, and on finding that the only stone present was fixed in the cystic duct, I concluded that its presence had occasioned hepatitis and catarrh of the common duct. The smooth regular border which the right lobe of the liver presented favoured this view. No doubt the ascites, the frequent pulse, and evening rise of temperature indicated a malignant origin. On April 7th I telegraphed to Mr. Lawson Tait, desiring his opinion with regard to treatment of the fistulous opening in view of the excessive flow of bile. He very kindly replied at once, and wrote to me saying that the condition was new to him, but that he suspected malignant disease. The sudden stoppage of the flow of bile from the fistula was no doubt due to perforation of the common duct, and to the same cause we may attribute the presence of blood in the abdomen. The occurrence of monthly bleeding from the gums, which was noted by the patient, cannot, I think, be regarded as in any way related to menstruation, when we consider the pathological conditions presented by the case.

POISONING BY COCAINE ADMINISTERED SUBCUTANEOUSLY.

BY BERNARD PITTS, M.C.

WITH reference to the annotation in THE LANCET of Dec. 3rd, on Poisoning by Cocaine, the following case may prove of interest. I am indebted for the careful notes to Mr. Calvert, assistant house-surgeon to St. Thomas's Hospital. My attention was called to the case in the out-patient room by Mr. Calvert as one of cocaine poisoning. At first sight the patient's condition suggested the probability of a nervous attack, but it was soon obvious that this was not a sufficient explanation. The symptoms shortly afterwards became alarming, and gave rise to grave apprehension as to the result. There is no reason to suppose that the injection in this case was made into a vein, and the preparation of cocaine was the same as had been used in other cases in the out-patient room. The drug is now in very general use for minor operations, and few cases have been recorded where toxic effects have ensued. I have several times noticed slight indications of constitutional effect, but used the drug oftentimes much more freely than in this case, without anxiety. I can now no longer regard the drug as free from risk, and shall be more cautious for the future, especially when the patient has not had the drug tried on him before, for there must doubtless be some peculiar idiosyncrasy in the subject when such marked symptoms arise.

The patient, a boy aged thirteen, came to the out-patient room at St. Thomas's Hospital on Saturday, Oct. 22nd, suffering from a suppurating sebaceous cyst situated in the middle of the forehead. This had previously been opened by a local practitioner some time prior to his application at the hospital, but the incision having healed the matter had reaccumulated. It was therefore decided to evacuate the contents and scrape out the interior of the cavity under cocaine. For this purpose two grains of hydrochlorate of cocaine were dissolved in thirty-five minims of water, and of this solution twenty-five minims were injected through two punctures, one on each side of and close to the abscess cavity. The solution was injected at 2.30 P.M. Within five minutes of the injection, the patient became pale and very restless, with hurried respiration and a rapid pulse (120). The abscess was quickly incised, the contents evacuated, the interior scraped, and the wound dressed. The symptoms shortly afterwards became alarming. The patient was exceedingly restless, constantly shifting his position, throwing his arms and legs about, and wringing his hands. The heart's action became tumultuous; the pulse at the wrist was irregular, rapid, weak, and almost imperceptible; the respirations were rapid, shallow, and irregular; and the pupils were dilated. The patient appeared in great distress; removed his collar and unbuttoned his shirt, so as to expose the chest. Meanwhile, half a drachm of aromatic spirit of ammonia was administered, and, the symptoms continuing, the dose was repeated a few minutes afterwards. Nausea and retching, with eructations, set in at 3.15 P.M., the patient complaining of great pain in his "stomach." This pain was markedly increased on firm pressure over the epigastrium, but was relieved by friction. Half an ounce of brandy was administered, and friction applied to the epigastrium. The patient's condition improved; the pulse, though rapid, became stronger, and the respiration slower and more regular. The dose of brandy was repeated, and a mustard poultice was applied to the epigastrium for fifteen minutes. The symptoms at 4 P.M. continued as before, but were less marked. The patient still complained of pain in his stomach, and lay on his left side with his legs drawn up. He said "he felt better," and was not so restless. At 4.45 P.M. he was removed to the ward, placed in a warmed bed, and hot bottles applied to his feet. He now improved rapidly. He was sick and vomited before 6 P.M., after which there was little to record.

The patient never lost consciousness, and was quite rational when spoken to throughout the persistence of the symptoms. The local anæsthesia was certainly not well marked at the time of the operation; afterwards it was not tested. Taking twenty-five minims of the solution as injected, this would give one grain and a half of cocaine, but owing to some of the solution being spilled and some escaping from the punctures on withdrawal of the syringe, it is in excess of the amount actually injected.

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

CONGENITAL MALFORMATION OF FOREARMS AND HANDS, WITH CONCOMITANT ATROPHY OF THE BICEPS AND BRACHIALIS ANTICUS MUSCLES.

BY G. C. WILKIN, M.R.C.S., L.S.A.

THE following case came under my observation whilst off the coast of China on board the steamship *Palamed*:—

The man, a Chinese coolie, was about five feet in height, and in appearance remarkable for his childish expression and the absence of a pig-tail, such hair as was present on his scalp being short, grey, and stubbly. His lower limbs and body were perfectly normal. His hands, both of which were small, consisted of the four fingers and their corresponding bones and muscles, the thumbs being absent. There was a difference in the arrest of development on the two sides. *Right side:* Carpus—slight trace of trapezium and scaphoid bones; entire absence of pisiform bone. Forearm—Styloid process of the radius absent. Styloid process of the ulna hypertrophied. Both bones dislocated backwards and outwards from the humerus. Humerus normal. Biceps and brachialis anticus small, but fairly well nourished. *Left side:* Carpus—Absence of trapezium and scaphoid, also of the pisiform bone. Forearm—Radius an inch and a half long, joining the ulna at its lower extremity, its upper extremity being dislocated outwards. Ulna from the junction of the radius to the styloid process hypertrophied; above this normal. Humerus convexly curved forwards and outwards. Entire absence of the biceps and brachialis anticus muscles. There was very slight power over the movements at the wrists, but the fingers were well controlled by their muscles.

The family history was difficult to obtain. He had no

Digitized by Google

brothers or sisters, and his father and mother, he said, were quite healthy and well developed.

The measurements of the two upper limbs are as follows:

		Right.	Left.
Arm	Length...	11 in.	10¼ in.
	Circumference ...	7½ in.	5½ in.
Forearm ...	Length...	6¾ in.	4¾ in.
	Circumference ...	6½ in.	5½ in.
Hand	Circumference round knuckles	7 in.	6 in.

ALOPECIA AREATA.

BY E. ST. GEORGE QUEELY,
MEDICAL OFFICER, MAYTOWN HOSPITAL AND PALMER DISTRICT, NORTH QUEENSLAND.

A VERY remarkable case of alopecia areata came under my notice in 1883, and although my patient thought it had disappeared some fourteen months ago, he has just returned with the disease appearing as bad as ever. As little or nothing can be derived from the different text-books on the subject, I thought some of the readers of THE LANCET might be interested in the case, and furnish me with some fresh mode of treatment. The following is the history.

J. E——, male, aged thirty-three, first came under my notice in November, 1883, and exhibited a bald spot about the size of a sixpence in the front of the scalp. It was circular, and had a peculiar ivory-white appearance, without pain or irritation. What struck him first was that the disease originally commenced under his chin and extended slowly round, removing the stubbles (he shaved regularly), and giving his lower jaw the smooth white appearance. This he overlooked, and did not get any advice until it commenced in the head. I first blistered the spot with liq. epispasticus, then used sulphurous acid and ordered tonic medicines. As the disease extended, my patient left for England. On the voyage several spots appeared, and on arriving in London he consulted Dr. J. Hutchinson, who ordered chrysophanic acid combined with white precipitate of mercury. This was used for some time, and as the spots by this time were very large, my patient had his head shaved, thinking by doing so he could better apply the ointment. From London he went to Glasgow, and there saw Dr. McCall Anderson. This gentleman examined his head carefully, and told him he thought it might be a long time before the hair would recover, and that the disease would spread further. He ordered tonics and the ungt. cantharides (P.B.). This treatment continued for some months, the head being kept shaved and the ointment applied night and morning. However, gradually the disease spread to eyebrows, moustache, pubis, and, in fact, all over the body, so that in about twelve months the man was perfectly denuded of hair, even to the few silky down ones on the fingers. Whilst in England he had a bad attack of intermittent fever, followed by herpes zoster and mumps. In 1885 white silky hairs (lanugo) appeared all over his head; these were replaced several times by a fresh growth, which became stronger and darker. In 1886 he left England for Queensland, thinking the disease cured, and each month the hair grew stronger and darker, and when I saw him on his return he had a good head of hair; his beard was also strong. Whilst in England he constantly wore a wig. He recently called on me in a great state of excitement to inform me that the disease had returned, and on examining him I found several spots again on his head having all the appearance of alopecia. I have been lately using the "liniment crinale" of Squire, but, I think, without effect.

Now, I should like to know if there is any cure for the disease, or if it is, like many others, incurable. I have examined the hairs, but could distinguish nothing to warrant it being called parasitic. The bulbs were atrophied and shrivelled, and in many the ends were split, resembling a brush. There were also some irregularities and nodular swellings of fat near the roots. The disease seems to me to be one of malnutrition of the scalp, but from what cause I know not. I should mention one peculiar fact: whenever the man bathes, or has cold or hot baths, on drying himself his skin becomes terribly itchy, this irritation lasting some time.

A RARE PRESENTATION IN MIDWIFERY.

BY T. PATTERSON DEVLIN, L.R.C.P. & S. EDIN.

A SIMILAR case to that related by Mr. Buchanan in your issue of Dec. 3rd, came under my notice. Early on the morning of Oct. 9th, 1884, I was sent for by the midwife. On arrival she informed me that the cord had been coming down, but that she had been able to keep it quite right. Upon examination I found this quite true, but that a hand was also presenting alongside the head. In a short time I was able to place the loop of the funis well up out of danger, then, having applied the forceps, I pushed the hand up over the face, and safely delivered a living child. There is no doubt that the life of the child was largely due to the midwife's early recognition of the condition of matters, promptly sending for assistance, and her close attention to the condition of the funis until I arrived.

Carlisle.

A Mirror OF HOSPITAL PRACTICE, BRITISH AND FOREIGN.

Nulla autem est alia pro certo noscendi via, nisi quamplurimas et morborum et dissectionum historias, tum aliorum tum proprias collectas habere, et inter se comparare.—MORGAGNI *De Sed. et Caus. Morb.*, lib. iv. Proœmium.

HOSPITAL FOR SICK CHILDREN, GREAT ORMOND-STREET.

TWO CASES OF DISEASE OF THE TIBIA IN WHICH THE KNEE-JOINT WAS INVOLVED IN ACUTE SUPPURATION; CONSERVATION; RECOVERY.

(Under the care of Mr. EDMUND OWEN.)

THESE cases were brought before the notice of the members of the Medical Society of London at the meeting on the 19th, a report of which appears on p. 1270. The notes were taken by Drs. Penrose and E. J. Lewis.

CASE 1.—A boy of seven years was admitted from an orphanage in May last, on account of a small sinus below the inner tuberosity of the right tibia, from which pus was constantly oozing. There was a good deal of thickening about the head of the tibia; the knee was flexed. On July 27th he was placed under chloroform, and Mr. Pitts scraped out an abscess cavity which started from the junction cartilage and extended into the upper epiphysis. By the middle of August the wound was almost healed, but soon after this the knee swelled up, and became hot and painful, and the boy's temperature ascended to 103·4°. It was evident that the ulceration in the epiphysis had extended through the articular lamella, and had implicated the knee joint. The boy was extremely ill, and, considering the old-standing affection of junction cartilage and epiphysis, the prospect of ultimately saving the leg did not seem bright. The suppurating joint was laid open by a bold horse-shoe incision, which passed through the ligament of the patella. The synovial membrane was found to be swollen and injected, and an ulcer was seen upon the inner articular cartilage of the tibia, through which a probe could be dropped into the original abscess cavity. The tibial abscess cavity and cloacæ were scraped out, and, together with the knee joint, were thoroughly washed with a weak mercuric solution. The joint was then drained through the head of the tibia, and through the popliteal space. Everything went on well; the wounds have entirely healed, and the boy is going about on crutches wearing a Thomas' splint. The knee is not quite straight—it could never be got so; and what may be the ultimate condition as regards movement it is at present impossible to say, for the joint has not yet been exercised in any way.

CASE 2.—A girl of nine years was admitted in July last with the following history. She had always been delicate; the school to which she had to walk every day was three miles from her home, she had consequently been much exposed to wet and cold. In February last she complained of pain at the right ankle, which showed a red

Digitized by Google

and very tender spot; the doctor called it "erysipelas." Two days later she became delirious, and in about a week the right elbow puffed up. In the meanwhile the leg was greatly swollen, and an abscess which had formed near the ankle was opened, as was also one which had formed near the elbow. After this the child, who had been delirious for more than a fortnight, was much relieved. For three months the leg was poulticed, and in June, a month after the arm had got well, an abscess appeared under the chin. Thus the history clearly showed acute periostitis of tibia, subperiosteal abscess and pyæmia—a tolerably common sequence in children. Had the doctor compared the tibiæ at the beginning of the disease, he would have found the affected one enlarged and tender, and would not then have taken the redness of the skin for erysipelas. Then, making an incision through the swollen periosteum, he would have cut short the disease, and would also have greatly diminished the risk of necrosis.

On admission the child was very ill; the leg was swollen from knee to ankle, but the joints were free. Several cloacæ, one of which was just above the inner malleolus, and another below the head of the tibia, led through to bare bone. Mr. Owen cut down through the thickened tissues and removed a sequestrum of the tibial diaphysis four or five inches long, remarking at the time that, considering the unfavourable conditions, local and general, he feared that amputation would soon have to be resorted to. However, the child did splendidly, and in about a month the wound was almost well. But then, as in the other case, the temperature ran up almost to 104°, the knee became large, hot, and tender, and aspiration showed it to be distended with flaky pus. It was concluded that suppuration had found its way from the line of the upper junction-cartilage into the knee joint; and on opening the articulation and turning up the patella, by dividing its ligament, as in the last case, an opening was discovered below the inner semilunar fibro-cartilage, through which a probe could be passed into the sequestral cavity. The case was treated as in the former instance, except that, as the sinus passed on the inner side of the epiphysis, the drainage tube was not run through the head of the tibia itself. The child made an excellent recovery, and, like the boy, is going about in a Thomas's splint, with the sound foot raised on a patten.

Remarks by Mr. OWEN.—These are two of the most important and interesting examples of joint disease which I have ever met with, and it is probably stating the case mildly when I say that many a limb has been amputated for a far less serious condition. The successful issue is to be ascribed to several circumstances, such as the absence of delay and temporising when it was found that the joint was actually involved in suppuration, the free exposure of the interior of the joint, the efficiency of the drainage (in each case a tube was passed through the posterior ligament and through the popliteal space), and the careful scraping and irrigation of the suppurating cavity and track. The dressings were of absorbent mercurial wool.

WEST HERTS INFIRMARY.

CASES OF SURGICAL INTEREST.[1]

(Under the care of Mr. F. C. FISHER.)

CASE 1. *Ankylosis of knee joint.*—C. F——, aged twenty, housemaid, was admitted on June 18th, 1885. The patient had scarlet fever ten years ago, followed by ankylosis of the right knee. Five years ago she fractured the right femur close to the knee joint. It was put up in plaster-of-Paris, and on removal it was found that an abscess had formed about the joint. The patient had been able to walk with a crutch up to three weeks ago, when she fell and bruised the knee, afterwards she was unable to bear any weight on that foot.

On admission, the right knee was flexed and fixed at an angle of 45°; above and to the inner side of the patella was an old scar, the result of an abscess. Measurement: right femur, two inches and three-quarters shorter than the left; right leg one inch and a quarter shorter than the left; the contour of the joint was lost, the depressions on either side of the patella being replaced by bulgings, over which there was tenderness. Extension was tried, but was useless. After consultation it was decided to operate.

On July 17th an exploratory incision was made under ether. The cartilages both of femur and tibia were disorganised, and the patella ankylosed in the inter-condyloid notch. The joint was then excised with Listerian precautions, but, owing to the depth of the ulceration, a good deal of bone had to be removed, leaving a large gap. There was a good deal of subsequent bloody oozing.

The case ran an aseptic course. Highest temperature 100°. No pus. Wound healed by primary union. Tubes entirely removed on July 30th.

Sept. 1st.—No bony union; parts rubbed one on the other and limb put up in plaster-of-Paris. Patient discharged, walking on crutches.

She was re-admitted on Dec. 4th, 1885, and plaster removed. Flail-like union; patient unable to lift the limb off the bed. With the patient's consent further operation was decided on.

Jan. 12th.—With Listerian precautions, the bones were cut down on, all fibrous tissue removed, and the bones refreshed. They were then brought together by two stout pure silver wires, and the ends battered down into the bones; a strip of skin, including the old cicatrix, was removed. The soft parts were then brought together, and the limb put up in a splint made out of Gooch's material, after the pattern described by Watson Cheyne.

The case again ran an aseptic course. Highest temperature 100·6° the day after operation. No pus formed.

Jan. 30th.—Parts quite healed, except at site of tubes.

Feb. 13th.—Firm bony union. Limb removed for the *first* time out of the splint, and encased in plaster-of-Paris.

March 10th.—Plaster removed. Can bear her weight on the foot.

In July, 1887, the patient presented herself wearing a high-heeled boot. She had walked eight miles at a stretch without a stick, and was able to do all housework, being quite able to kneel down on the one knee to scrub a floor. She was greatly pleased with the result.

Remarks by Mr. FISHER.—The total length of shortening was about seven inches, four inches of which existed before operation, due to the fracture and arrest of development of the leg. The silver wires (which must be of quite pure silver) were used with two objects. First to keep the bones approximated, and secondly to prevent subsequent displacement backwards. To attain this second object, I think the following mode of insertion is worth following—viz., to make the holes in the tibial section quite near the posterior surface; those in the femoral section being more anterior in this way, when the wires are drawn together the tibia is lifted out of the popliteal space, counteracting all tendency to subsequent displacement backwards. To those who have not used the splint mentioned I can very strongly recommend it; once put on, it need not be removed, and the comfort both to patient and surgeon during dressings is immense.

CASE 2. *Vesicalcalculus; supra-pubic lithotomy.*—J. S——, aged three, was admitted on July 21st, 1887. During the last few months, whenever the child has passed urine, he has crossed his legs and complained of pain in the penis. His mother thought that he passed urine more frequently than natural.

On admission the patient was a well-nourished child, who passed urine every hour and a half, sometimes very small in quantity, crossed his legs as described, and had pain on urination. The prepuce was long and narrow. There was no blood or albumen in the urine.

July 29th.—Chloroform was administered, and a stone detected with the sound. After a consultation it was decided to perform supra-pubic lithotomy.

Aug. 4th.—Chloroform was administered; the rectum distended with a small pear-shaped indiarubber bag holding 4 oz.; the bladder emptied and injected with about 6 oz. of boric acid solution, and the penis ligatured. The bladder now formed a rounded eminence, reaching rather more than half way to the umbilicus. An incision was made from the pubes upwards for two inches and a half; having exposed the loose fat immediately above and behind the pubes, by scratching through this, the fibres of the bladder were easily seen, and then the loose tissue covering the bladder was gently pushed upwards by the finger nail, the nail scratching through any slightly resisting cellular tissue. A sharp hook was passed into the bladder, and an opening about half an inch made with a scalpel in the middle line. The contents of the bladder rapidly ran out, the forefinger of the left hand was introduced, and the stone detected and hooked upwards towards the wound; by a

[1] Read before the West Herts Medical Society on Oct. 12th, 1887.

Digitized by Google

little manipulation with the other hand the stone was gently squeezed out of the bladder wound. No ligatures were required; the abdominal walls were brought together with silk sutures; a drainage tube was put in the bladder. The bladder was not sutured. The wound was dressed with salicylic silk and iodoform.

The bladder was daily washed out with boric acid solution by the wound and per urethram.

8th.—Drainage tube removed.

12th.—All sutures have cut their way out, leaving a healthy granulating sore.

17th.—Passes urine per urethram when standing up, free from all pain.

Sept. 15th.—The wound has now been healed for two or three days, and the boy has been running about the ward quite well. He is free from all pain, and was discharged as cured.

Medical Societies.

PATHOLOGICAL SOCIETY OF LONDON.

The so-called Hendon Cow Disease and its relation to Scarlet Fever in Man.

AT the special meeting on the 15th inst. the following discussion took place on the above subject, introduced by a paper by Professor E. Crookshank, which was published in full in our last issue.

Professor BROWN desired to state the position which he occupied with regard to this inquiry. When Mr. Power's report concerning the Hendon cow disease appeared, he criticised his conclusions on the same basis as those of any other documents which came under his notice. He found that that report was based on negation. There was absence of any evidence of contagion by human agency. If the human contagium had presented itself, Mr. Power's postulates would never have been drawn. Was it more probable that there was an undiscovered source of human contagion than that the cow herself had developed something in her system which could give rise to human scarlatina? It had been hinted that there was some friction between the various Governmental departments, but so far from that being the case, he was willing, with the sanction of the lords of the Council, to place the whole of the resources of the Agricultural Department at the disposal of the Medical Department and of the profession generally for the purposes of this investigation. Mr. Power's report had inflicted a shock on the dairy interest, and as a result he had directed the present investigation. After a great delay he was able to get intimation of several outbreaks of the disease. The cause of the delay was partly the fear of giving information after the publication of Mr. Power's report, and partly the fact that the veterinary surgeon rarely heard of the outbreak, the farmer simply coming to him for a pot of ointment to treat the sore teat. That the disease was looked upon among farmers as of no account was shown by the fact that the affected cows sold in the market at a fair price. A few brought to the metropolis with the disease had been slaughtered, but the majority went to mix with other herds in various parts of the country. The pock which developed on the teat was "spoilt" by the handling of the milkers, and developed into a filthy sore. In some six or seven outbreaks during the last two months (for it was very prevalent at the present time), this eruptive disease of the teat had not been coincident with scarlatina; this might be only a singular coincidence. He did not profess to connect this disease with the Hendon cow disease, for he never saw the latter. Recently 604 cowsheds had been inspected in the metropolis, and over 9000 cows examined, but no eruptive disease had been discovered. His experience was that in rural districts dairy farms were often very dirty, whilst dairies in town were, as a rule, patterns of neatness and cleanliness. On the bacteriological aspect of the question he was silent, but he was unprepared to hear that this disease was really cow-pox. It seemed desirable, from his point of view, that it should be put under the Contagious Diseases (Animals) Acts, which would make it an offence to sell milk from a diseased animal.

Dr. BUCHANAN said that Professor Brown seemed to take it for granted that, given two febrile diseases, each associated with a micrococcus presenting certain characters in nutrient material, the two diseases must be the same. Professor Crookshank and Professor Brown had never seen one of the diseases they affected to diagnose, and the unity of the affections had been affirmed on resemblance of some only of the characters, not all. In the Hendon cases results of the post-mortem examination had been recorded, but they had heard nothing of the necropsy of Dr. Crookshank's case. His conclusion was that Professor Crookshank was in possession of some curious cases of cow-pox arising apparently spontaneously, and the result of inoculation into human beings would be awaited with interest. He supposed there might be some varieties of this disease called by Professors Brown and Crookshank *the* disease.

Dr. KLEIN said that Professor Crookshank had compared the disease he had seen with the outbreak at Hendon on the strength of Dr. Cameron's report, but that account was based on information derived from a variety of people in different localities. Dr. Cameron says that he is informed that human inoculation has happened, but this did not occur at Hendon, for there was not a single case there of infection of a milker, and there was no fever, no primary eruption, and no vesiculation. The ulcers and sores observed on the Hendon cows were different from those on the cows from Professor Crookshank's investigation which had been placed at his disposal. The ulcers in the Hendon cows were deeper, smaller, and healed up more rapidly; in eight or ten days the crust was gone. In the Wiltshire cows there were large irregular superficial ulcers; there was no "substance" in them, merely a slight granulating surface underneath the scab. A cow sent from Edinburgh had in its lesions greater similarity with the Hendon than with the Wiltshire cows. The milk from the herd of Edinburgh cows had been supplied in a district in which between forty and fifty people had been attacked with sore-throat and fever. In regard to the organisms, he was surprised that Professor Crookshank said that these microbes, because they appeared to agree in certain particulars, were therefore the same thing. It was too short a time yet to judge of these differences; one would be found to grow a little slower, the colonies were a little smaller, and there were other small differences. As an illustration of this he would quote the micrococci of septicæmia, scarlatina, and erysipelas; all behaved much alike in cultivations, but on inoculation the septicæmic organism at once differentiated itself. There were many streptococci which, similar under the microscope, differed in rate of growth, size of colonies, opacity or translucency, and behaviour in different cultivation media. He could say positively that the organism from the Hendon cow disease was not the same as the organism from Professor Crookshank's cases. From cow No. 1, which had a mammary abscess, he got an organism which he planted in agar-agar, Brand's extract, and peptone mixture, but it refused to grow; whereas, the organism from the Hendon cows grew readily in such a mixture. Then, again, cow No. 1 had no visceral lesions; whereas, in the Hendon cases there was lung, spleen, and kidney disease. Professor Crookshank's cases looked much like real cow-pox, and were most probably so; his pictures corresponded to Ceely's figures, and it would be interesting now to test and see if the calf would not take animal vaccine. Dr. Klein quoted an instance in which two horses were affected with a disease which looked like variola equina; the eruption healed and left no pitting. One of the grooms developed a vesicle on his thumb. Inoculation of lymph from this vesicle did not produce cow-pox in calves, ponies, or donkeys. It was therefore a disease which only resembled variola in some particulars. So in the present instance, though vesiculation and ulceration were present, inoculation alone would prove the affection to be true cow-pox.

Professor CROOKSHANK, in reply, said he had not personally observed the Hendon cow disease, and Dr. Klein who had made the post-mortem on the first of his cases had already told the result. His own account had followed as closely as possible Dr. Klein's narrative of the Hendon disease. He had said that the microscopical appearances and characters on cultivation were identical with those of other streptococci. To his mind the evidence put forward by Mr. Power was a clever hypothesis, and Dr. Klein, by introducing the organism, had made that hypothesis a working one. He had yet to study the effect of inoculation in animals. He had succeeded in growing the organism in agar-agar and in broth. He regretted that no drawing had been published of the

Digitized by Google

original Hendon disease. On the farm from which his cases were drawn were eleven milkers: four old men had had the disease before, and did not contract it again; the other seven were lads, and had all contracted it. He would be glad to give all who were interested in the subject every opportunity of working at it. If Dr. Cameron's report did not refer to the Hendon cow disease, he thought some official statement to that effect should be made by the authorities of the Local Government Board.

Sir JAMES PAGET felt sure that in the future the disease could not well be overlooked. There was a great necessity that diseases in the cow should be studied by careful pathologists, and Mr. Ceely's papers and drawings would yield most valuable material for the investigation, and were deserving of the closest study.

Rare Forms of Fracture of the Lower End of the Femur.—Vertical Fracture of Head of Tibia.—Rare Fracture of Acetabulum, with Dislocation of Head of Femur into the Pelvis.—Partial Perforations of Skull-cap in cases of Cerebral Tumour.—Pathology of Sarcoma of Sole of Foot.—Rickets in Lion's Skull.

An ordinary meeting of this Society was held on Tuesday last, Sir James Paget, Bart., F.R.S, President, in the chair.

Mr. BULL showed a specimen of Fracture of the Lower End of the Femur, extending into the knee joint. It was removed from a cabman aged fifty-six, whose thigh was amputated owing to the suppuration in the knee joint which ensued on the hæmorrhage into the joint due to the injury. A large slice of bone had been broken off the lower end of the femur from the anterior surface, the condyles being split laterally and longitudinally. The fracture had become united by callus. A somewhat similar fracture was known to occur in the patella, but its occurrence was, perhaps, unique in the femur.

Mr. D'ARCY POWER showed a specimen from the museum of St. Bartholomew's Hospital of Simple Comminuted Fracture of the Head of the Tibia, with a longitudinal fracture extending upwards through the internal tuberosity into the knee joint. The patient was a woman aged seventy-six, who fell down a flight of twenty steps and was found with her leg doubled under her. The fibula was shattered just below the neck. The main interest of the specimen consisted in its illustrating the mode of occurrence of longitudinal fracture in these cases; it was clear that the fracture resulted from the driving of the lower into the upper fragment.

Mr. TIMOTHY HOLMES showed a specimen of Fracture of the Acetabulum, with Dislocation of the Head of the Femur into the Pelvic Cavity. The man, aged about sixty, had fallen from a height of fifteen feet on to his side in the trochanteric region; the thigh could be flexed and crepitus felt; there was one inch of shortening; the great trochanter was deeply sunk, and reached just above Nélaton's line. The patient died in a few hours. The head of the femur had passed through the bottom of the acetabulum, and had broken the os innominatum into many pieces. A somewhat similar specimen was shown before the Society by Mr. Moore. Reference was made to cases quoted by Sir Astley Cooper, and also to another instance, probably of a similar nature, but not examined anatomically. In Mr. Cutler's case the head of the femur was not driven into the pelvis. An accurate diagnosis in these cases was perhaps not impossible, though it had not been made in any of the known recorded cases. The reduction of the fracture was possible.—Mr. FREDERICK TREVES thought the case exhibited the mechanism by which the fractures were produced, and this was by the force being sent through the great trochanter, the head being driven as a wedge through the quadrilateral thin portion of the acetabulum and so splitting up the two arches of the pelvis. In reply to Sir James Paget, he said he explained the difference of result in different cases by supposing that the head of the femur was in contact with different parts of the acetabulum at the moment of the receipt of injury. Sometimes the acetabulum would be merely starred, and at others the head of the femur would be driven through, according, perhaps, to the degree of violence. If the head rested against the thick part of the acetabulum, then the neck of the femur would be broken.—Mr. TIMOTHY HOLMES partially agreed with Mr. Treves, but considered that the mechanism of fractures was frequently inexplicable.—Mr. TREVES suggested that a series of artificial fractures on the dead body might point out the *rationale* of these cases.—Sir JAMES PAGET had attempted years ago to fracture bones so as to imitate ordinary solutions of continuity, but without success. He asked that some of the younger members of the Society would undertake a series of experiments of the kind suggested.

Dr. ORMEROD showed a Skull with Partial Perforations from a case of cerebral tumours. About thirty holes were scattered over the frontal and parietal regions on both sides, varying in size from a quarter of an inch in diameter downwards, extending through the inner table, and in some instances almost completely perforating the skull. Actual perforation was observed during life over the right eye; this perforation was enlarged in the course of a surgical operation for removal of the tumour, and therefore not now visible. The dura mater exhibited clean-cut perforations corresponding to those in the skull. There was roughening of the internal table between the perforations, and in some places general thinning of the skull. The holes were seen at the necropsy to be due to small soft tumours sprouting from the surface of the brain. The large surgical hole was blocked by a slough when the tumour had been removed, and behind this the frontal lobe was entirely softened. The choroid plexus of the ventricles was infiltrated with pus, which, tracking into the left temporo-sphenoidal lobe, formed a large abscess there. The patient was admitted under Dr. Andrew into St. Bartholomew's Hospital with general symptoms of cerebral tumour. Some left-sided paralysis appeared soon after. He became unconscious, and remained in that state for over a year, being kept alive by nasal feeding. Shortly before death a perforation occurred over the right eye; the hole was enlarged, and the tumour partly removed.

Mr. F. TREVES showed a Tumour from the sole of the foot as a contribution to the early history of malignant growths. The specimen came from a man aged fifty-six; in the sole of the foot the swelling had been in existence for thirty years, and had steadily increased. It had a circumference of about ten inches, and measured about three inches and a half across; the skin was sound everywhere, except at one spot near the little toe, which was softened and the seat of more active growth. Injury, irritation, and exposure to cold had all operated upon the tumour for many years, and it had been walked upon for thirty years; so that age would seem to have most influence in the development of the tumour. The malignant new growth was of the size of a horse-chestnut. The primary tumour of fibrous tissue could be seen to be infiltrated with a new growth arranged without order or method. The notion that the tumour took on a degeneration into a malignant character was not supported, for it seemed that the malignancy was due to an actual addition rather than a conversion or true metamorphosis.—Dr. COUPLAND referred to the uterine fibromata in which malignant growth was not developed from the muscular fibre.—Mr. BLAND SUTTON spoke of the tumours of tumours, as when certain dermoid tumours became the seat of malignant growths; the ovary might become the seat of epithelioma, and perhaps of other neoplasms.—Mr. GODLEE did not think that malignancy was always an addition, but an actual change might occur in the elements of a tumour, as when recurrent fibroids became more malignant.—Sir JAMES PAGET, whilst agreeing with the main argument, pointed out that a new growth takes on properties from the tissue in which it grows.—Mr. TREVES detailed the histology of certain warts, in which there appeared to be a direct conversion of the individual cells into epithelioma.

Mr. BLAND SUTTON exhibited specimens illustrating a peculiar effect of Rickets upon the Skulls of Lions. Last session he showed some similar specimens, in which the bones of the skull pre-formed in membrane were those most affected in rickets; this applied to all mammals. The carnivora possess an ossified tentorium which normally is of the thickness of writing paper. When the skull is thickened by rickets this bony tentorium is also affected, the enlargement giving rise to pressure symptoms and some curious effects on the brain. The specimens previously exhibited showed the changes which occur in the brains of cubs; the enlarged tentorium presses upon the vermiform process of the cerebellum, and this compression occludes the fourth ventricle and intercepts the inter-ventricular communications leading to hydrocephalus, with well-marked symptoms, general paralysis, and death. When the thickening of the tentorium occurs at a later date the effects upon the brain

Digitized by Google

are somewhat different. The large tentorium presses upon the vermiform process of the cerebellum and obliterates the fourth ventricle, but instead of causing extreme dilatation of the third lateral ventricles in the cub, we find these cavities are but little larger than usual. The effects upon the floor of the fourth ventricle are somewhat different, for an examination of the cerebellum and medulla in longitudinal shows that the abnormal pressure of the vermiform process causes erosion of the floor of the fourth ventricle, and in one of the specimens this portion of the cerebellum is accommodated in a distinct shallow groove. The differences may be accounted for by the unyielding character of the cranium at the age of two years in lions, as compared with the accommodating nature of the sutures and fontanelles in the cub. The lions from which the specimens were obtained were paraplegic for many weeks before death, and in one the tail became gangrenous and sloughed. On the hind limbs were three large ulcers comparable to bed-sores. In reply to Sir James Paget, he said that rickets was not found in animals in the wild state. John Hunter's specimens were probably obtained from menageries. An extinct form of whale (Pachycanthus), found in a large tract of country near Vienna, was shown by Paul Gervais to have signs of rickets, and with a remarkable narrowing of the spinal canal to a mere chink.

The following card specimens were shown:—

Dr. PERCY SMITH: Syphilitic Arteritis from General Paralysis of the Insane.

Dr. PENROSE: 1. Multiple Renal Calculus in a child aged nine years and a half. 2. Pericellular Cirrhosis of Liver in a child aged three months, suffering from congenital syphilis.

Dr. MONTAGUE MURRAY: Infective Endocarditis affecting both sides of the Heart, with Patent Ductus Arteriosus, in a woman aged thirty-six.

Dr. D. F. DREWITT: Gangrene of Leg occurring in the fourth week of typhoid fever.

Mr. LEOPOLD HUDSON: 1. Atrophic Cirrhosis of Liver with large Prominences, due to fatty infiltration. 2. Hæmorrhage into a large Cyst in a Cirrhotic Kidney.

Mr. STEPEN PAGET: Fibro-sarcoma beneath the Pectoralis Major.

MEDICAL SOCIETY OF LONDON.

Acute Arthritis.—Gastric Ulcer.—Psoas Abscess.—Mitral Stenosis.

THE meeting on Dec. 19th was a clinical evening. The chair was taken by the President, Dr. J. Hughlings Jackson, F.R.S., at 8.30 P.M.

Mr. EDMUND OWEN gave a clinical demonstration on two cases from the Great Ormond-street Children's Hospital. These cases are described in full in our present number under the heading "Mirror of Hospital Practice."—Mr. ADAMS said that trephining the head of the tibia often prevented the abscess spreading to the joint. He looked upon the cases rather as subacute; the acute cases being either pyæmic or traumatic, usually necessitating amputation, if not, leading to ankylosis.—Mr. BOWREMAN JESSETT referred to a case of acute periostitis of the tibiæ which involved both knee joints, and in which amputation was followed by a successful result.—Mr. PAGE advocated trephining the head of the bone where symptoms of abscess existed, in order to obviate arthritic complication.—Mr. H. ALLINGHAM preferred to open the joint in such cases by a vertical incision, splitting the patella.—Mr. PYE thought osseous ankylosis would be preferable to imperfect movement in a damaged joint.

Dr. ORD demonstrated the case of a coachman, aged sixty, in whom there was a strong family history of Gastric Ulcer, and who himself presented many symptoms of that affection. He was emaciated and cachectic, suffered from pain after food, relieved by vomiting, the vomit containing blood. The symptoms had entirely disappeared under treatment, consisting of a mixture containing subnitrate of bismuth, carbonate of potash, and tincture of belladonna, with infusion of gentian, together with a soft bland diet. The diagnosis rested principally on the absence of palpable tumour, the effect of treatment, and the history of many years' gastric suffering. The ulcer differed from those found in young women, in being larger, less regular in outline, and shallower, and in possessing a rounded, rather raised, never hard edge. In cases of undoubted carcinoma he had found that a mixture of bismuth and iodide of potassium greatly mitigated the pain.—Dr. SIDNEY PHILLIPS said that cases of unduly pulsating aorta had been connected with hæmatemesis and melæna without gastric ulceration.—Mr. JESSETT had found iodide of potassium and alkalies useful in gastric catarrh.—Dr. KESER inquired if tropæolin, described by Van den Velden, had been used by Dr. Ord as a test to distinguish between the vomit of ulcer and cancer.

Mr. BERNARD PITTS exhibited two cases of Psoas Abscess treated by lumbar incision. The first was a boy aged twelve, who had pain in his lumbar spine for several months, followed by formation of abscess, which had been evacuated by a free lumbar incision. A finger introduced into the wound detected extensive carious excavation of the front of the bodies of several lumbar vertebræ. The boy was kept at rest in bed for eight months, when well-marked angular curvature was manifest. For the last six months a poroplastic jacket had been worn, and the discharge, which was now exceedingly small, was received into an iodoform dressing changed once weekly. The second case was a man aged twenty-nine, who had a fluctuating swelling in the left groins of ten weeks' duration, apparently unassociated with injury or spinal disease. The groin swelling was opened by a small incision and a large counter-opening made in the loin. Two months afterwards he left the hospital with the wound soundly healed. Both were treated antiseptically. Mr. Pitts spoke of the almost uniform success now obtained in dealing with psoas abscess, more particularly in children. In the boy the lumbar incision enabled the extent of the mischief to be accurately gauged, and prolonged rest in bed commensurate with its gravity to be decided on. It would have been difficult to have included safely and comfortably an inguinal incision in an antiseptic dressing. The abscess in the second case, he thought, was more probably due to some carious spot which the finger failed to reach than to primary suppuration in the psoas, consequent possibly on strain. He stated that he would never open a psoas abscess unless he could obtain a lumbar drain; he regarded syringing unnecessary unless the pus were offensive or curdy.—Mr. OWEN considered absolute rest in bed better treatment than supports for angular curvature.—Mr. WALSHAM had seen cases cured by two or three aspirations without incision.—Dr. ORD and Dr. S. WEST spoke of the value of aspiration in cases of empyema.

Dr. SAINSBURY showed a patient, a girl of nineteen, with cardiac disease, in whom there was at the apex a rough diastolic murmur—post-systolic—accompanied by thrill. There was likewise a blowing apex systolic bruit, and the second sound at the base was reduplicated.

CAMBRIDGE MEDICAL SOCIETY.

A MEETING of this Society was held on Nov. 4th, Mr. E. Carver, F.R.C.S., President, in the chair.

Dr. RANSOM read the notes of six cases of Diphtheria, all of considerable severity. Albumen was present in all cases, the amount varying more or less directly as the severity of the case. All were followed by paralytic symptoms. All recovered except one, a girl of fourteen, who died quite suddenly on the eighteenth day apparently from syncope, due perhaps to paralysis of the heart muscle or formation of clot; the throat had been well for several days, and the girl seemed to be rapidly recovering, when one evening she had an attack of vomiting, followed by some slight epigastric pain and dyspnœa, death occurring the next morning quite suddenly. One case was complicated with pertussis and the extension of the diphtheria into the larynx; this case recovered. Possibly the pertussis was of some use in preventing tracheal obstruction. All the cases were treated with liq. ferri perchlor. fort. in hourly doses, and hourly painting of the throat with a weak, watery, solution of glycerine of tannin. Attention was called to Löffler's researches on the bacillus of diphtheria as reported by Fraenkel, in defence of the theory of the local origin of the disease and the resemblance of the diphtheritic membrane to the primary syphilitic sore, and the treatment employed defended on this ground.

Professor HUMPHRY showed a specimen of Congenital Sacral Tumour removed from a girl, aged twelve, under his care in Addenbrooke's Hospital. It was a mass the size of the girl's head, consisting mainly of fatty tissue, with a circle of bone, thought rudely to represent a pelvis, and a long

Digitized by Google

jointed bony part, thought rudely to represent a limb. The bony growth extended into the pelvis between the ilium and ischium, but was not connected with either. Professor Humphry did not remove the deeper portion, being of opinion that, as the mass was congenital and not increasing with the girl's growth, that which remained would not create any inconvenience.

Mr. FRANCIS read a paper on Œsophageal Diverticula, in which he classified them into the following groups: (*a*) Congenital: Reference was made to the chief theories as to their occurrence—as analogous to œsophageal diverticula occurring in some of the Sauropsida and in ruminant mammals (forming the first two compartments of the "stomach"); or as fœtal varieties, analogous to the œsophageal diverticulum from which the larynx, trachea, and lungs were formed; or as failure in closing of bronchial cleft at its pharyngeal end; and he remarked on the absence of evidence to show that these diverticula were, at any rate usually, congenital. (*b*) Diverticula associated with stagnation ectasia, depending on stricture of the tube below, and analogous to certain diverticula of the intestine, bladder, and rectum. (*c*) Pressure diverticula, usually occurring near the junction of the œsophagus and pharynx. (*d*) Traction diverticula, usually occurring near the tracheal bifurcation; analogous to diverticula occurring rarely in the bronchus or intestine. He referred to the different methods of production of these diverticula, by the contraction of inflammatory deposits outside the œsophagus, or by the action of the musculus pleuro-broncho œsophageus of Hyrtl and Cunningham, or by the absence of support to the œsophagus below the bifurcation of the trachea, as advocated by Struthers. A specimen was shown, removed from a patient in Addenbrooke's Hospital, under the care of Professor Latham, after death from phthisis, in which a large abscess cavity at the bifurcation of the trachea communicated with the œsophagus and simulated a true traction diverticulum.

MIDLAND MEDICAL SOCIETY.

A MEETING of this Society was held on Nov. 23rd, the President, Mr. Ross Jordan, in the chair.

Foreign Body in Bronchus.—Dr. HAWKES read notes of a case of a child, aged one year and eleven months, who was admitted into the Children's Hospital on Oct. 22nd with the physical signs of obstruction of the left bronchus, and collapse of that lung. On Oct. 16th, while eating a portion of rabbit, he was observed to be choking. The mother dislodged a piece of bone from the back of the mouth and the symptoms of asphyxia ceased, leaving, however, a short cough. This continued for a few days, after which time he was taken to the hospital and admitted. Tracheotomy was performed and every effort made to dislodge the obstructing body, but without success, and the child died on Oct. 26th. At the necropsy one of the caudal vertebræ of a rabbit was found in the bronchus leading into the upper part of the left lung. The left lung was much collapsed, and in a condition of croupous pneumonia.

Tumour of Superior Maxilla.—Mr. AUGUSTUS CLAY showed a tumour, the size of a hen's egg, which he had removed by enucleation from the antrum. There was a history of incessant toothache on that side for four years. Twelve months before the operation a swelling the size of a marble appeared at the upper part of the gum. In six months this had grown rather rapidly, and bulged out the cheek in the usual characteristic manner. The other cavities were not encroached upon. An exploratory puncture was made, and a piece removed for microscopic examination; it was found to be a simple fibroma. A week later the growth was turned out of the antrum, after a small skin incision and an opening through the thin bony wall had been made. The patient was discharged on the nineteenth day after the operation, and up to the present time (twelve months) there has been no recurrence.

Resection of portion of Thyroid.—Mr. MARSH showed a boy, aged fifteen, on whom he had performed resection of part of the thyroid gland. On admission to the Queen's Hospital he was found to have a large bronchocele (simple hypertrophy) of only three months' growth. Each lobe was equally enlarged, and a piece the size of a small orange was situated over the trachea. The pressure symptoms being very marked, Mr. Marsh decided to resect the portion of the gland in front of the trachea. A median incision was made, and with some little difficulty the trachea was cleared, a piece of thyroid the size of an orange being removed. The hæmorrhage was not excessive. The relief afforded was immediate, and the patient rapidly improved in health. The remaining part of the gland became much softer and visibly smaller, evidently atrophying. He was discharged with the wound healed on the nineteenth day after the operation.

Hereditary Optic Atrophy.—Dr. SUCKLING showed a man aged sixty-three suffering from double optic atrophy, entailing complete blindness. He gradually lost his sight when he was fifty, and he states that blindness runs in his mother's family. His mother became blind at the age of fifty; his sister was blind; a female cousin on his mother's side is quite blind. The pupils are small and respond to light. There is no history of syphilis or nervous disease, or any signs of locomotor ataxia.

Fracture of Spine.—Dr. SUCKLING also showed a man aged seventy-six who three months ago had fallen down two stone steps on to his back. He went about for a week without pain, and then had severe shooting pain round the left side. On examination the spine of the tenth and eleventh dorsal vertebræ were found to be prominent and tender on percussion, there being also marked angular curvature. With five weeks' rest in bed all pain and tenderness disappeared, the prominence remaining.

Papilloma of Larynx.—Mr. JORDAN LLOYD showed a papillomatous tumour which he had removed intralaryngeally from a female aged thirty-five. The woman had suffered from hoarseness and paroxysmal dyspnœa for more than seven years, and had been treated for "throat consumption" by several practitioners. The growth was pedunculated and flatly globular in shape, measuring five-eighths of an inch transversely and half an inch in depth. It grew from the lower edge of the left vocal cord. Attempts to seize it with forceps failed, and it was then rubbed off its attachment by means of a piece of dry sponge fastened to the end of a laryngeal probe. Relief to symptoms was immediate. The operation was performed last May, and there is no sign of recurrence.

Brain lacerated by "contre-coup."—Mr. LLOYD also showed a brain from a healthy young man who was supposed to have fallen downstairs on to the back of his head. The injury to the scalp was over the left lambdoidal suture. No symptoms of any kind were present for sixty hours, and then he developed typical Jacksonian epilepsy in the left face, tongue, and jaw muscles, with a progressive paralysis of the left arm. He was trephined over the right fissure of Rolando, on the opposite side of the head to the seat of injury, and a large blood-clot removed. The symptoms were relieved for a few hours; they then returned, and he died comatose about sixty hours after the operation. The necropsy revealed a separation of the right lambdoidal suture with a fracture extending from it obliquely across the right parietal bone, squamous portion of temporal, into the middle fossa of the skull, and terminating between the right lesser wing of the sphenoid and orbital plate of the frontal bone. There was no injury to the brain at the seat of external injury, but part of the right frontal and temporo-sphenoidal lobes were "pulped." There was slight crushing of the front of the right parietal lobe. There were several localised extravasations into grey matter of the convolutions about the fissure of Rolando.

Monstrosity.—Mr. H. S. COOK showed a case of fœtal monstrosity: male twins joined together from the ensiform cartilage to the umbilicus. The mother was delivered naturally, the presentation of the first being a vertex and the second a footling. One lived two days and a half, and the other three. They were both fed with milk, both micturated, but only one had a motion. The living child, after the death of the other, was so feeble that any operation of separation was out of the question.

Dr. SAVAGE read a paper on Pelvic Cellulitis.

NORTHUMBERLAND AND DURHAM MEDICAL SOCIETY.

A MEETING of this Society was held on Nov. 10th, Dr. G. H. Hume in the chair.

Adenoid Vegetations in Pharynx.—A girl was exhibited by Dr. LIMONT who had improved under treatment.

Blocking of Central Artery had occurred in a patient exhibited by Mr. WILLIAMSON. No cardiac or kidney disease existed. There was a history of injury to the head,

Digitized by Google

which was thought to have displaced a patch from some diseased cerebral vessel.

A specimen of *Intussuscepted Bowel* was exhibited by Dr. JAMES DRUMMOND. The symptoms resembled those of irritant poisoning.

Genu Valgum.—A man thus suffering had been successfully operated upon by Mr. MORGAN.

Dupuytren's Contraction.—A man, aged forty, in whom Mr. MORGAN had to divide the flexor tendons, had now good use of hands. The disease began fifteen months ago.

Extra-uterine Fœtus removed successfully by Gastrotomy.—A specimen was exhibited by Mr. MORGAN which was said to have been of twelve months' formation. The cyst had to be stitched to the abdominal wound, and prolonged hectic fever followed; but the patient ultimately made a good recovery. — Mr. Rutherford Morison, Drs. Murphy and Hume, and Mr. Page took part in the discussion, each alluding to cases that had occurred in his own practice.

Abscess of Brain.—Mr. BLACK exhibited a specimen removed from a boy whom he had trephined. The convulsions and left-sided paralysis present before the operations had not been relieved by it.

Liver in Phosphorus Poisoning, removed from a woman who died thirty-eight days after taking the poison, was exhibited by Dr. DRUMMOND. It showed cirrhotic changes. Leucine and tyrosine had never been present in the urine.

Cancer of Stomach.—Dr. DRUMMOND exhibited two specimens. In one the disease was at the pyloric, in the other at the cardiac, end of the stomach.

Sarcomatous Growth from Mediastinum.—Dr. OLIVER exhibited a specimen of a round-celled sarcoma removed from the body of a young man aged twenty-six, who had good health until three months ago, then dyspnœa and hæmoptysis. The growth involved the pericardium and extended to the thyroid.

Electrical Treatment of Uterine Fibroids.—Dr. OLIVER also exhibited Apostoli's apparatus, and commented upon its application in the case of a lady at present under his care suffering from a bleeding uterine myoma.

Idiopathic Tetanus.—Mr. PAGE read notes of a case at present under his care. He advocated the purely nervous nature of the disease, regarding it as dependent upon an exaltation of the polarity of some portion of the grey matter of the spinal cord. Alluding to Shakespear's experiments, he considered the medulla oblongata as the seat of the poison in traumatic tetanus, and he hoped that the experiments which Shakespear and others had carried out in regard to this affection would be repeated in the proposed comparative anatomy and pathological laboratory about to be established in the new College of Medicine in Newcastle.—Drs. Limont, Philipson, and Heath, and Mr. Clement Stephenson, joined in the discussion.

GLASGOW OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY.

THE usual monthly meeting was held in the Faculty Hall on Wednesday evening, Nov. 23rd, Dr. Abraham Wallace, President, in the chair. J. McGregor Robertson, M.D., C.M., and H. St. Clair Gray, M.B., C.M., were duly elected members of the Society. There was a large gathering of the general profession in response to a special invitation to hear Mr. Skene Keith, of Edinburgh, who read a paper on "The Treatment of Fibroid Tumours of the Uterus by Electricity," and Dr. J. McIntyre, who gave a "Demonstration of Apparatus used for Electro-therapeutics." Mr. Keith gave the details of six fibroid cases treated successfully as to reduction of size of tumour, mitigation of pain, and cessation of metrorrhagia, and the results in fifty-eight cases (1350 applications), whereof fifty-two had been greatly benefited. Dr. McIntyre recounted the various forms of electric force and the different methods whereby these are rendered applicable to practical therapeutics, together with the methods at present used for measuring the current as to intensity, quantity, and rate, and the terms of measurement. He also gave an interesting demonstration of batteries and modes. Both papers were cordially received and discussed.

Reviews and Notices of Books.

The Life and Letters of Charles Darwin, including an Autobiographical Chapter. Edited by his Son, FRANCIS DARWIN. Three Volumes. London: John Murray. 1887.

THE appearance of these volumes will be welcomed by all those who desire to know something of the public and private life of a man whose slowly matured convictions, enunciated in measured and weighty terms, have not only effected a revolution in natural history, but have been applied with almost identical results to many other departments of human knowledge. The three volumes are respectively devoted to his early life up to 1854; to an account of the history, publication, and spread of his work on the "Origin of Species"; and to the various works which appeared in quick succession from 1863 to 1883.

The family from which Charles Darwin arose were formerly substantial yeomen residing in the northern part of Lincolnshire, close to Yorkshire. His father was a doctor, who, from the various anecdotes that are told of him, must have been a man of great acuteness of intellect; and he himself was born at Shrewsbury on February 12th, 1809. At a late period of his life a German editor appealed to him for an autobiographical notice, and thinking the subject was one that might interest his children, he drew up a short account of his life and character, which, though short, constitutes one of the most interesting parts of the work. From this it appears he had the misfortune to lose his mother at the early age of seven, just after he had been sent to school at Shrewsbury. He states that he was a lad of inquiring mind, fond of collecting all sorts of objects, such as shells, seals, coins, and minerals. Amongst his earlier recollections was his disposition to *invent*, if that term may be applied to lying; and he gives as an instance that he once gathered much valuable fruit from his father's trees, and, after concealing it in his shrubbery, ran in, in breathless haste, to spread the news that he had discovered a hoard of stolen fruit, which, after all, was not far beside the mark. It is interesting to note that although a pupil in one of the best schools in the country, and at a time when Dr. Butler was head master, he in after life considered that the school as a means of education to him was a perfect blank, and that the only qualities he possessed, which at this time promised well for the future, were that he had strong and diversified tastes, much zeal for whatever interested him, and a keen pleasure in understanding any complex subject or thing. In contrast with the modern side or department which has been established in some of the great schools in England, he observes that, on its becoming known that he worked with his brother in spare hours at chemistry, he was once publicly rebuked by Dr. Butler for wasting his time on such unprofitable subjects, and stigmatised as a *poco curante*, a term that, not being understood, troubled him greatly. On leaving school, he was sent, in 1825, to Edinburgh University, with a view of entering the medical profession, but the dreariness of the lectures, his unconquerable aversion to dissection, and his mental agony in witnessing operations, then of course performed without chloroform, led him to spend most of his time in the pursuit of natural history. He formed friendships with Dr. Coldstream, with Grant (afterwards Professor of Comparative Anatomy in University College, London), and with Macgillivray. In 1828, all thought of medicine being given up, he proceeded to Cambridge with the intention of entering the Church; and as he says himself, considering how fiercely he has been attacked by the orthodox, it seems ludicrous that he once intended to be a clergyman. This intention was never given up, but died a natural death when, on leaving Cambridge, he joined the *Beagle* as naturalist. In later life, he adds, the humorous

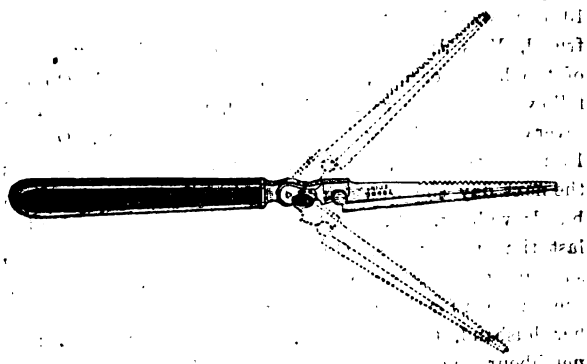
Digitized by Google

of a German psychological society asked him earnestly by letter for a photograph of himself, and some time afterwards he received the Proceedings of one of the meetings, in which it appeared that, after public discussion of the shape of his head, one of the speakers had said that he had the bump of reverence developed enough for ten priests. He passed well in the poll, and obtained his first taste for scientific work from friendly personal intercourse with Henslow, the botanist, and Sedgwick, the geologist. He was appointed through Henslow's instrumentality naturalist to the *Beagle* in 1831, and was away from England for nearly five years, his impressions being recorded in "A Naturalist's Voyage round the World." In this work the dawn of his future labours is sufficiently apparent. A few years after his return from this voyage, in the course of which his health became much impaired, he settled at Down, where with his wife and family he remained till death closed the scene on April 19th, 1882. He was buried in Westminster Abbey, accompanied to the grave by many of his oldest friends, and by a large number of interested and mourning spectators.

A point that is particularly worthy of notice in Darwin's life is the relatively short period of the day he devoted to actual work. His son states that after breakfasting alone at about 7.45 he went to work at once, considering the hour and a half between 8 and 9.30 one of his best working times. An interruption for an hour followed, and then he set to work again from 10.30 to 12, by which time he considered his day's work over. The rest of the day was spent in brief exercise, and in having novels, history, and travels read aloud to him. Indeed, novels seem to have had a strong attraction for him, probably affording relaxation of the mind from the tension of severe thought.

Letters, as a rule, are dull reading, if only from their interrupted disconnected character; but we can assure our readers that Darwin's letters are exceptionally interesting. They show the whole process of development of his great theory; how earnestly he brooded over the subject; in how many aspects he viewed it; how desirous he was to obtain information on all points that might serve to illustrate or correct it; how fearful he was that he should weary his most intimate friends, Lyell, Hooker, and Henslow, by constantly reverting to it. They show his naturally lively disposition and his thorough perception of fun—as, for example, this postscript in a letter to Lyell "Our ancestor was an animal which breathed water, had a swim bladder, a great swimming tail, an imperfect skull, and undoubtedly was a hermaphrodite. Here is a pleasant genealogy for mankind!" They show at the same time the truth of Bacon's aphorism that reading makes a full man, writing an exact man, and speaking a ready man. Darwin both read and wrote much, but he on several occasions expresses his gratitude to others who replied to criticisms, declaring that they had used arguments he had forgotten, though he had forged them, and that, as in the case of Asa Gray, they knew his works better than he did himself. He did well to keep away from meetings of societies, where his temper and health would alike have been impaired; his adversaries might here have obtained a temporary victory, and he would have deprived himself of the immense advantage of submitting all adverse arguments to the calm and cold consideration of the study, where he could summon up a thousand facts to controvert the views of his opponents or to support his own.

The great work on the "Origin of Species," on which his fame mainly rests, appeared on Nov. 24th, 1859. The number of copies printed was 1250, and all were sold on the first day, when an edition of 3000 was immediately prepared. Copies were sent to Hooker, Lyell, Huxley, Wallace, Agassiz, and many other leading men, and his letters to them and their replies to him are full of interest. More than one of his friends, whilst passing high eulogiums on the manner in which he had treated his subject, warned him of the storm of criticism that was in store for him. The storm came. The book was greeted in many quarters with an outburst of wrath, scorn, and indignation, which he evidently felt, but bore up manfully against. At this time it was almost impossible for anyone who was thought likely, either by his independence of thought or by his eccentricity, to accept the new theory, to meet his friends at dinner or other social gathering without being asked whether he believed in this new-fangled nonsense, or whether he had made up his mind from what animal he was descended. To those who can recall this period, the change in the public mind which has resulted from the toning effects of familiarity and the influence of authority is very remarkable as well as encouraging.



The life of Darwin shows how much may be accomplished by a man of fair but not extraordinary talents, when these are supplemented by great industry and earnest study in some one direction, and the lesson thus taught is within the power of most if not all men to practise. We recommend Mr. Darwin's life of his father to all our readers, and cordially compliment him on the way in which he has fulfilled the task that naturally devolved upon him.

Burroughs' Medical Diary.—We have received a copy of Burroughs' Medical Diary for the coming year, and are able to speak highly of its merits. Convenient in size, well bound, and containing information of special interest to members of the medical profession, it deserves and will doubtless have a large sale. Its appearance is late, and owing to this circumstance its proprietors have decided to make a large reduction from the price originally proposed.

New Inventions.

REVERSIBLE NASAL SAW.

THIS instrument has been designed for the removal of cartilaginous and bony obstructions in the nasal passages. The advantages it possesses are: fineness of the blade, and, by means of a screw at the junction of the blade and the handle, a reversibility which enables the operator to work from above or from below, or at any angle that may be

necessary. The serrated edge extends along from one-half to two-thirds of the blade, so as to avoid injuring the skin at the entrance to the nares. I have hitherto had two sizes made—one for fine, the other for coarser work. The maker is Mr. Young, Forrest-road, Edinburgh.

Edinburgh. G. HUNTER MACKENZIE.

ST. DALMAS HOSPITAL STRAPPING.

MR. DE ST. DALMAS has submitted to us a sample of his hospital strapping. It is spread on good stout "holland," is very adhesive, and appears to fulfil all the necessary conditions. The plaster is stated to be entirely free from resin, and to be unirritating.

THE LANCET.

LONDON: SATURDAY, DECEMBER 24, 1887.

THE trial of Surgeon-Major CROSS for the wilful murder of his wife by poison commenced on the 14th inst., and, after lasting the whole of three days and the greater part of a fourth, resulted in a verdict of guilty, prisoner being sentenced to be hanged on the 10th prox. This was almost a foregone conclusion at the preliminary stages of the case before the coroner and magistrates in August. The main facts, as disclosed in the evidence given at the trial, were briefly as follows. The accused, PHILIP HENRY EUSTACE CROSS, was a retired army surgeon-major, having obtained the L.R.C.S.I. in 1848, and being now about sixty-three years of age. He was married to the deceased lady (whose maiden name was LAURA MARY MARRIOTT) in 1869, she being at the time of her decease forty-six years of age. Soon after their marriage he left the army, and they went to live at Shandy Hall, near Cork, being in comfortable circumstances, having a family of five children, and they would appear to have lived happily together until the close of 1886. At that time the prisoner began to treat his wife with indifference; and having formed an adulterous intimacy with a Miss SKINNER, a lady who had been governess in his family for three months, he began to treat his wife with cruelty, threatening and cursing her. He left home last March, and was proved to have stayed at a hotel in Dublin with Miss SKINNER, they living as man and wife under the assumed name of OSBORNE. Up till the end of April last the deceased, though somewhat delicate, had fairly good health, and was seen by a gentleman (who had known her for twelve years) walking about a field, looking well, and expressing herself as feeling well. On May 8th she was at church; on the 9th she was out visiting; and on the 10th she was first attacked with—to use the words of a lady friend, Miss JEFFERSON, who was on a visit—"spasms of the heart, cramps, vomiting, and diarrhœa." On the following day she remained in bed, where she continued several days, suffering from the same symptoms. On the 18th she was better, and had a walk with Miss JEFFERSON; the next day she went to church, it being Ascension Day, but drove back. On the 22nd (Sunday) she was out for the last time in her life. On the 24th she was again in bed, suffering from the same symptoms as before. On that day she was seen for the first time by a medical man other than her husband, this being Dr. THOMAS GODFREY, a near neighbour, and an uncle by marriage of the prisoner. He saw her in bed, CROSS being present, his visit lasting about fifteen minutes. He had been told by CROSS that his wife was suffering from diarrhœa, and the impression conveyed to his (Dr. GODFREY'S) mind was that she was suffering from a bilious attack. He suggested that she should have three or four grains of calomel, and an aperient on the following morning. It is always easy to be wise after the event, and cases of criminal poisoning generally come to the notice of medical practitioners in so insidious a manner as to escape notice. Had Dr. GODFREY pushed his inquiries further than he appears to have done, its true nature might perhaps then have been diagnosed, possibly even in time to save the poor lady's life. She had a wet cloth round her head, and when asked by him the reason why, she made no reply. The intermittent character of the symptoms, and CROSS'S statement that the vomiting and diarrhœa were much better that day, were suspicious. Dr. GODFREY'S evidence would appear to have surprised both the learned judge and counsel for the defence, while the Attorney-General did not re-examine him. He was never asked to see her again, but, living so near, it does seem remarkable that he should never have called. No other medical practitioner saw her, no nurse was procured, and all the evidence as to symptoms came from non-professional witnesses, Miss JEFFERSON'S being especially valuable. This lady kept a diary, from which most of the preceding facts have been given, and on the 26th she began to be alarmed. On the 27th and 28th she noticed that the deceased's eyes seemed irritated and inflamed; the latter also complained that she could not see distant objects, read the paper, or write. On the 29th she was getting weaker and was drowsy; she was constantly vomiting. On Wednesday, June 1st, Miss JEFFERSON saw her alive for the last time; she was quite intelligent, able to express her wishes, give orders, and to describe her state. The exact time of death could never be ascertained, as only the prisoner was present; but according to his statement made to the servants it occurred about 1 A.M. on Thursday, June 2nd. The deceased was not dressed in the usual grave clothes, and the prisoner assisted two of the servants in laying her out. The clergyman who had visited her was not allowed to see her when he called a second time, and other friends were kept away from her from alleged reasons which were not correct. On June 3rd the prisoner registered the death as due to "typhoid fever," he being both the informant and the certifying medical attendant. Next—and this is still more remarkable—the body of the unfortunate deceased was buried on the Saturday after, at 7 o'clock in the morning, the prisoner having tried to arrange for the burial an hour earlier. He now stated to a neighbour that she had died from heart disease. On June 17th he married Miss SKINNER in London; and, the police having obtained information justifying an inquest, the body of the deceased was exhumed on July 24th, in the presence of Dr. CROWLEY (who identified it) and Dr. CHARLES YELVERTON PEARSON (Lecturer on Medical Jurisprudence in Queen's College, Cork). The result of the post-mortem examination effectually disproved that typhoid fever was the cause of death. The body was remarkably well preserved, considering the time of year and the excessive heat; the heart was found healthy, and all the appearances were consistent with death from irritant poisoning. Dr. PEARSON found crystals of white arsenic in the contents of the stomach, and obtained 1·74 grain of arsenic from this organ alone. He obtained 1·28 grain of arsenic from the liver, and found it in the spleen and kidneys. In the small intestines he found strychnine, the quantity of which he estimated at less than one-hundredth part of a grain. He was subjected to a very severe cross-examination by the prisoner's counsel, and was recalled to be questioned by the jury just before they found

Digitized by Google

their verdict. Mr. Justice MURPHY, in his charge to the jury, paid Dr. PEARSON a very high compliment, which was well deserved. It would appear to be the first occasion on which Dr. PEARSON has been required to make a post-mortem inspection, and to chemically examine the viscera in a case of arsenical poisoning. Whilst his evidence leaves nothing to be desired, it would have been more comfortable for him, and would have strengthened the case for the Crown, had there been a second analyst with previous experience of such work, either working jointly with him or independently. Such a one could surely have been found in Dublin. In PALMER'S case Dr. SWAYNE TAYLOR worked in conjunction with Dr. OWEN REES; in LAMSON'S case Dr. THOMAS STEVENSON had the co-operation of Dr. DUPRÉ; in PRITCHARD'S case Dr. PENNY of Glasgow and Dr. (now Sir) DOUGLAS MACLAGAN were engaged; and many other instances could be adduced where the same practice has been adopted. It only remains to add to the already strong case against the prisoner CROSS that he was proved to have purchased a large quantity of arsenic for the alleged purpose of sheep-dipping.

The case affords another melancholy illustration of what has been seen before—that among members of a noble profession are to be found criminals of the deepest dye. It is some consolation to reflect that in this case, as in those of PALMER, LAMSON, and PRITCHARD, the prisoner was not in actual practice, having retired from the army and never having practised as a civil surgeon. It is satisfactory to notice that there has been no delay in bringing him to justice, or any undue leniency displayed towards him by his professional brethren. His crime resembles that of PRITCHARD in its motive, each having been led to commit it in order that he might remove out of the way a wife who was an impediment to marriage with a female with whom an adulterous intercourse had already existed. It also resembled that of LAMSON in its utter audacity and recklessness of consequences, there being less cunning and more clumsiness than are displayed by the average poisoner. But it surpasses all previous cases in its wanton cruelty, its cold-blooded deliberation, its disregard of all the decencies of social life. The marriage of the second wife almost before the first could have been cold in her grave was aggravated by the fact that it took place in the very same church in which, eighteen years ago, he had married her whom he had treated so cruelly and so foully murdered. So aggravated was the case in all its surroundings, that his counsel were almost unable to make any defence. It was truly a desperate case.

In conclusion, it is to be observed that the trial was conducted with the greatest ability by all concerned, the speeches of counsel and the summing up of the learned judge being models of what they should be. The reports of the local papers are extremely good, giving question and answer, the only means by which medical evidence can be perfectly understood.

THE debate at the Pathological Society upon Professor CROOKSHANK'S paper, although confined to a very limited number of speakers, including the heads of the two Governmental departments concerned with the health of animals and of man, was yet as much as could be expected or desired in the present stage of the subject. To a large extent the discussion turned upon the question whether the disease investigated by Professor CROOKSHANK, and stated by Professor BROWN to be widely prevalent at the present time, was the same affection as that with which the cows at Hendon were attacked, when the milk they furnished appeared so conclusively to have been the medium of scarlatinal infection. Professor CROOKSHANK boldly proclaimed his belief in their identity. Professor BROWN was less positive; but neither of them was in a position to affirm it from personal observation, since they had not actually *seen* the "Hendon cow disease." Dr. BUCHANAN was therefore within his right in declaring that the Society had no concern with this question; it could pronounce only upon the nature of the disease which Professor CROOKSHANK had apparently shown was an example of spontaneous cow-pox. Dr. BUCHANAN, however, did not ignore the question of identity, but pointed out that the two affections, although similar, did not present evidence of unity upon all points, and therefore could not be considered as identical. Dr. KLEIN, who had seen both diseases, was convinced of their essential difference on grounds to which we shall presently refer. In view of such divergent opinions, it is impossible to avoid joining in the regret expressed by Professor CROOKSHANK that the report of the Hendon cow disease was devoid of any illustrations which could convey, so far as pictorial representations can, the naked-eye characters of the affection to the minds of those who had not actually seen it.

The leading questions, then, before the Society may be resolved into these: 1. What evidence is there for and against the identity of the Wiltshire cow disease and that of Hendon? 2. What evidence is there for the Wiltshire affection being indubitable cow-pox? 3. If the new disease (which, by the way, from Professor BROWN'S remarks, would seem to be remarkably common—so common as to be thought nothing of by the dairy farmer, and thus rarely brought under the notice of the veterinarian) be neither one nor the other, under what category of bovine maladies does it come? We will deal with each of these in turn, and endeavour to show how impossible it is at present to arrive at a definite conclusion. First, then, let us consider Dr. KLEIN'S reasons for disputing the identity between the two affections. He considered that Dr. CAMERON'S description of the Hendon disease should not be taken as accurate, for it was not solely based on personal observation; and, rejecting a piece of hearsay evidence adduced by that gentleman, he denied that there was a single case of infection of the hands of a milker of the Hendon cows. Professor CROOKSHANK found in his cows very strong evidence of contagion, but the transmission to man was limited to those who were unprotected, like the lad who was brought to London with well-marked vaccinal eruption. Dr. KLEIN averred that the characters of the ulceration in the Wiltshire cows, which Professor BROWN had given him the opportunity of seeing, were different from those present in the Hendon cows, for in the latter the ulcers were deeper, smaller, and more rapid in healing. Incidentally he stated that in a cow sent lately from Edinburgh through Professor BROWN there

Digitized by Google

was a greater approximation to these characters, and he heard that the milk of this cow was suspected of being the source of an epidemic of sore-throat. But he maintained, further, that the microbe discovered in the discharges from the ulcers was a different one in the two cases. He did not doubt the close similarity in many of their characters, but he pointed to many other forms of streptococci, which closely resembled each other, differing, however, in some points as to their mode of growth, the media in which they could be cultivated, and their effects when inoculated. Truly, to the uninitiated in bacteriology the points of difference between the two forms of streptococci in dispute seem very small indeed. Dr. KLEIN had failed to cultivate the streptococcus of the Wiltshire cow upon a special agar-agar peptone in which the streptococcus of the Hendon cow grew with avidity. Professor CROOKSHANK had not proved any difference in his cultures, and when Dr. KLEIN questioned if he had applied the crucial test of his own "Brand extract agar-agar peptone," Professor CROOKSHANK replied to the effect that Dr. KLEIN should make further trials of this medium before basing his opinion of non-identity upon such cultivations. When bacteriologists differ who shall decide? But Dr. KLEIN had other grounds for his view, which consisted in the existence of well-marked visceral lesions in the affected cows at Hendon which were absent from the other cows that had been sent to the Brown Institution by Professor BROWN. On clinical, pathological, and bacteriological grounds, then, he declared against the unity of the two diseases. Professor CROOKSHANK frankly admitted that the post-mortem appearances in those animals that had as yet been examined were not identical with those in the Hendon disease; but neither can it be held that the visceral lesions described by Dr. KLEIN were different in any essential part from those met with in septic poisoning. As to the clinical characters, Professor CROOKSHANK certainly did not see the Hendon disease, but neither did Dr. KLEIN see the Wiltshire affection in its earlier and more characteristic stage. The upshot of the contention must, then, apparently rest upon the bacteriological point, which, it will be admitted, is a very fine one, but of which the importance is not to be measured by its minuteness. The question is not decided, and we can hardly agree with Dr. BUCHANAN that it is one which ought not to have been raised, although it may well be that further evidence is likely to be adduced in the matter of the relationship to scarlet fever, which *is*, after all, *the* great issue at stake.

Apart from this knotty point, the interest of Professor CROOKSHANK'S investigation lay in the evidence he adduced to prove that the disease he investigated was true cow-pox, which Dr. BUCHANAN admitted he had long been on the look-out for, and which appears to have been singularly absent from the herds for a generation or more. Professor CROOKSHANK referred to HERING'S classification of the eruptive diseases of cattle, and showed that there were only two of the numerous affections described by that author which could be confounded with the disease he had studied, the one being cow-pox, the other the trivial blister-pox. He had no difficulty in showing that the disease was not the latter; and from the facts he gathered in his inquiries at the farms and mainly from the evidence furnished by the lad above referred to, he concluded, with some reason, that (1) the disease is common, (2) that it is highly contagious, and (3) that it is vaccinia. Professor BROWN confirmed the statement that it is extremely common, and that among the farmers it goes by the name of "cow-pox"; but yet that it is cow-pox—true vaccinia—has never been hitherto hinted. This question also is still *sub judice*. Those best informed on the characters of vaccinia declared that the pustules produced in the calf which Professor CROOKSHANK exhibited to the Society had none of the characters of vaccinia, and we understand that experiments are now in progress for crucially testing the point. We come, therefore, to the third question, If it be not vaccinia, what is it? Common as it is, contagious as are its properties, it must be a disease which, though closely simulating vaccinia, has hitherto escaped description by such faithful students of the complex diseases of the cow's udder as CEELY and HERING. If this be so, it is perhaps somewhat of a reproach to veterinarians that it has been overlooked; and we are glad to have Professor BROWN'S assurance that the disease will be placed under the provisions of the Contagious Diseases (Animals) Act, for then there is every probability of its being thoroughly described and studied. It is time, too, that such steps should be taken, for the sake of the animals and for the milk-consumer. It comes as a revelation—and by no means a pleasant one—that hitherto milk especially country milk, must have been obtained for distribution in large quantities from animals suffering from diseases of the udder, which become ulcerative from the manipulations of the milkers; but Londoners will be glad to hear that the thorough system of inspection of the metropolitan dairy-sheds is such that "real" London milk is free from the liability to contamination with the morbid secretions of the ulcerated udder. Apart from the vexed question of scarlet fever being directly transmitted from the cow, or the interest attaching to the re-discovery of vaccinia, the debate has elicited the gratifying fact that two great sanitary departments are devoting their attention to the removal of a grave source of danger to public health in the contamination of the milk supply.

THE publication of the "Life and Letters of Charles Darwin," has stimulated anew the interest always felt alike by scientific thinkers and the general public in the great doctrine with which his name will be always associated. It has been said that DARWIN was our greatest scientific genius since NEWTON, and it may be affirmed with equal truth that since the enunciation of the law of gravitation no principle has been propounded so novel so far-reaching, so pregnant with truth and suggestiveness, as the evolution hypothesis. Yet evolution remains a hypothesis, rather than a well-defined and thoroughly established doctrine. This is admitted even by Professor HUXLEY, the boldest champion of evolution in the days when it had a hard fight for a hearing, and now its greatest surviving exponent. In his recent article in the *Nineteenth Century* he claims for evolution only the position of a probable hypothesis, but a hypothesis which accumulating evidence renders every day more probable, and which has successfully withstood all the efforts put forth to accomplish its disproof and rejection.

Digitized by Google

Yet the assertion that evolution is a hypothesis only, and not an established doctrine, may easily mislead. It is a hypothesis if we regard it as a complete scheme into which all biological and cosmological laws must be made to fit; but, on the other hand, if we define evolution as a working principle widely operative in the field of nature, but of which we cannot precisely define the scope and limits, then evolution is no longer a hypothesis, but an ascertained truth which dominates every department of the field of scientific research. In other words, there is a something—a method, a principle—which we call evolution, and of which it is no longer permissible to deny the existence, but we must await further light before we can affirm that this method or principle is all-pervading and capable of affording an adequate and final elucidation of all the phenomena of life. We may illustrate the distinction by noting the contrast afforded by the very different reception accorded to DARWIN'S two great epoch-making volumes—the "Origin of Species" and the "Descent of Man." Although his teaching excited an alarm and opposition almost unparalleled in the history of science, nothing could be more remarkable than the rapidity with which his doctrine of species gained the adhesion of the leading thinkers of the day and permeated the whole atmosphere of scientific thought. That preliminary triumph has been the gauge of a final victory. The Darwinian doctrine of origin of species, so patiently elaborated by its author and expounded with such modesty and yet with such irresistible cogency, is now, in its main outlines at least, beyond the reach of cavil. Far different has been the fate of the doctrine of the "Descent of Man." That charming volume is instinctively felt by the impartial reader to be ingenious rather than conclusive, to raise a plausible theory rather than to establish a secure doctrine. It consists, in fact, of a long chain of analogical reasoning, for which the most ardent partisan will not claim more than that it suggests a possible explanation of the facts in question. The "Origin of Species" irresistibly bears down all opposition by the mighty force of accumulated argument, and by the calm confidence with which all objections are met and overthrown. The "Descent of Man," on the other hand, rather titillates the fancy than convinces the judgment.

For the present, then, the attitude of the scientific world is one of almost universal acceptance of evolution as a working hypothesis of unparalleled value and suggestiveness, but of reserve towards it as regards its final issues and ultimate limits. Whatever may be the final form assumed by the doctrine of evolution, we owe an immense debt to DARWIN for having unlocked some of the most mysterious recesses of nature and shown us the way of future hopeful advance. His teaching has been of untold value in bringing order into the chaotic mass of scientific material, and in suggesting methods of inquiry which have proved most fruitful and profitable. In physiology, especially embryology, and in pathology, its value has been altogether incalculable. To withdraw the conception of evolution from the domain of science would now seem to us quite as impossible as to return to the Ptolemaic system of astronomy. Just as NEWTON bound the spheres together by his great hypothesis, so DARWIN has succeeded in uniting in one the multiform phenomena of life. If, as has been said, "the end of science is the detection of unity," few doctrines have so just a claim to be reckoned scientific as the doctrine of evolution.

The opposition to evolution has been due in no small measure to a mistaken notion as regards its correct interpretation. It has been often forgotten that it explains processes, not origins; that it elucidates the *method* of creation, but has no explanation to offer as to its *cause*. The recognition of evolution leaves the argument for and against a Creator just where it was, although it undoubtedly modifies our conceptions of His modes of operation. It was one of the chief merits of COMTE as a thinker that he clearly perceived that science could only explain processes and transitions, and was unable to grapple with the question of causes. Hence, quite consistently, he ruled out all inquiries into causes as unscientific. In like manner the doctrine of evolution, correctly understood, has nothing to say about causes, and the evolutionist can have just as elevated a conception of a First Cause as the man who vaguely misapprehends evolution as a sort of substitute for a Creator.

It is pleasing to note that the angry controversies which once raged round the name of DARWIN have felt the mitigating influences of the softening hand of time. No one now seriously doubts the lofty character and absolute integrity of the great naturalist; no one denies him the tribute of supreme genius. He has erected a great landmark upon the shifting sands of human progress, and amongst earnest seekers after truth his fame will ever be of the greatest.

CONGENITAL defects of sight due to visible changes in the ocular fundus or disease of the optic path are numerous. Mr. NETTLESHIP, in his lectures delivered at the Royal London Ophthalmic Hospital, has done good service by drawing attention to the varieties of congenital and infantile amblyopia. Congenital syphilis may produce hyalitis from inflammation of the choroid or retina, and cases occurring in infants a few months old were mentioned. The prognosis in choroiditis occurring in hereditary syphilis is fairly good, if treatment be begun tolerably early. Choroidal disease is not so easy to detect in infants, on account of the absence of pigmentation about the patches and the naturally pale colour of the choroid at the earliest period of life. When choroiditis occurs later in hereditary syphilis, during or after the period at which keratitis occurs, when the hair and skin, and with them the choroid, have usually darkened, there is often extreme pigmentation of the patches, even more than in choroiditis in adults. Mr. NETTLESHIP gives valuable advice on the method of testing the vision of infants, and his remarks are worth quoting. "The chief things to notice are: whether the child turns its eyes towards the window, or follows the flash of the mirror in the dark room (or, what comes to the same thing, turns its head away, or blinks its lids under the same tests); the presence or absence of nystagmus; and the state of the pupils." He believes that healthy infants usually look at a bright light thrown steadily into the eyes a day or so after birth, but that from three to six weeks' education is necessary to enable them to follow a moving object in such a way as to give the appearance of intel-

Digitized by Google

ligence or "noticing." "If the infant's eyes oscillate rhythmically, or even wander constantly though irregularly, the sight is almost certainly bad, for we know very little of primary nystagmus from nervous disease in infants." The state of the pupils is of secondary importance, because the natural range of pupillary action in infants seems to be less than it is when the eye has attained full development. It is also pointed out that in children the light reflex may be present, even though the child be absolutely unconscious of light. A caution is given, in the examination of the pupils in infancy, not to touch the face or head, and so not to provoke movements of the head or eyelids. Besides syphilitic choroido-retinitis and hyalitis, Mr. NETTLESHIP recognises three other groups of infantile amblyopia. Microcephalous infants with premature closure of fontanelles and sutures may have gross choroiditis, apparently not syphilitic. Failure of sight may come on without papillitis during an illness diagnosed as meningitis, but not ending fatally. The fourth group comprises cases of blindness in infants without history of acute cerebral symptoms, and frequently without ophthalmoscopical change. In every case of infantile blindness it is important to observe the shape and size of the cranium as compared with the face, and the condition of the fontanelles and sutures; to inquire fully into the question of congenital syphilis, and of any acute illnesses the child may have had; of defective sight or intellect, or other cerebral or spinal disease in any kinsfolk, and of consanguinity of parents; and it must be remembered that an infant may be very well nourished, although syphilitic. The fact that in blind infantile idiots the pupils may react to light would seem to show that the optic nerve contains pupillary or reflex as well as visual fibres.

Hypermetropia, being due to imperfect development, is usually attended with defect in the acuteness of vision. It is possible for slight or even temporary defect of sight to excite nystagmus in an infant predisposed to it, and the amblyopia may be rendered permanent and possibly increased by the oscillation, and thus may be explained some embarrassing cases of nystagmus with amblyopia. Albinos also afford examples of the combination of defective acuity of vision with nystagmus, and yet probably neither condition is associated in them with any particular kind of refraction, though nearly all are more or less ametropic; albinism is not necessarily accompanied by amblyopia, but on the other hand, an albinotic infant may seem almost totally blind. Common retinitis pigmentosa, though not present at birth, invariably goes slowly on, once it has begun, to blindness, and in its later stages is complicated by posterior polar cataract and incurable progressive deafness. Mr. NETTLESHIP constructs a seventh group of cases of infantile amblyopia, having an affinity in pathogeny to retinitis pigmentosa, and not distinguishable from it if only the actual subjective symptoms be considered, but having, nevertheless, important differences. In this malady the night-blindness is stated to have been present from the earliest childhood, seems to be stationary, and does not appear to have the same pathological associations as the other disease; and some of the patients become deaf. The ophthalmoscopical appearances consist chiefly in irregularity of the pigmented epithelium and the presence of scattered minute white dots. The early presence and stationary character of the symptoms in this group of cases suggests that the choroidal and retinal changes are probably of intra-uterine date. In the eighth group of cases day-blindness of congenital origin is the chief feature, and is attended with colour-blindness as well as defective perception of form. The ophthalmoscopical changes are altogether insignificant; in these particulars it is complementary to the cases last considered.

Besides the groups above mentioned, there remains a number of cases in which defect of sight without any sign of disease is confined to one eye. In retro-bulbar neuritis and in disease of the optic nerve resulting from injury the reflex action of the pupil is interfered with, but not in the cases now being considered. The defect of vision may be very trivial, or so high that only large objects can be seen; it may be perfectly remediable with glasses, in which case there is almost always anisometropia, and the defective eye is nearly always the more ametropic of the two. Glasses may only partly remedy the defect, or they may not help at all. Squint may have been present at some period, usually convergent, but this has been cured by operation or has disappeared without treatment; in others, again, convergent or divergent squint of the amblyopic eye is still present. Finally, Mr. NETTLESHIP adduces facts and considerations to show that neither the theory that amblyopia in cases of hypermetropia is due to suppression of one image, nor the view that amblyopia is dependent on congenital imperfection of an eye or visual centre when one eye is concerned has been proved; but that whilst the former view requires proof not yet given, there is much evidence, both direct and indirect, in favour of the latter.

As the time draws nearer for the consideration of the various proposals for forming a new University or degree-granting institution in London, the various bodies interested, and the public in general, are taking a more active interest in the question. By the 16th prox. all petitions and objections must be lodged before the Privy Council, and it is understood that their consideration will begin at once, and that there will be no further delay. The next meeting of the Convocation of the University of London is fixed for January 17th, and the question is sure to be debated there also, on the motion of the Annual Committee expressing approval of the action of the Senate in opposing the movement for forming a Teaching University by the junction of University and King's Colleges with the metropolitan medical schools. Professor HENRY MORLEY has given two valuable lectures on the subject at the London Institution, and has clearly pointed out, from the sides of art and literature, how numerous, but how unorganised and chaotic, are the various educational agencies now existing in London, and has made some valuable suggestions for blending them into an organised whole. In his lecture, as in a pamphlet published some time ago, Professor MORLEY points out that he would prefer to include these bodies with the existing University by adding some new machinery to work with the present system. "The work of the London University had been done as thoroughly as any human work could be done," says Professor MORLEY; and surely this is the very best ground

Digitized by Google

for not interfering with the present arrangement by imposing on it work of an entirely different character. If a new Teaching University were established, it should be as distinct as possible from the existing one; in fact, it must do the work which the present University threw overboard when it opened its examinations to the whole world without requiring certificates of training or attendance on lectures. Such a University would have a good and separate mission, and would not weaken or impair the one now existing. One body would ensure due training, the other would, as now, keep up a high examination standard, and many pupils would avail themselves of the advantages of both. The objections against the new Teaching University relied on in the statement by the Senate of the University of London appear to us to be singularly weak. The Privy Council is desired to stay its hand, because Convocation and the Senate are engaged "in the consideration of a plan for giving to the professors in the institutions from which graduates proceed an organisation and a larger influence in the counsels of the University."

It is not likely that this scheme will yet see the light; in fact, it cannot be passed by Convocation and the Senate until after the hearing of the petitions by the Privy Council. Again, as this scheme can only be a slight modification of those of Sir PHILIP MAGNUS and Lord Justice FRY, every one practically knows what it will amount to. It cannot be so framed as to satisfy the need for a Teaching University, managed by teachers, without at the same time arousing the jealousy of the graduates towards the teachers. In fact, nothing of the kind will be attempted, and Boards of Studies, consultative only and without any real executive powers, are the only opportunities for influence offered to the teachers. Moreover, the union of country institutions with metropolitan ones, as now proposed, is altogether contrary to the ideas suggested by the Association for forming a Teaching University *in London*. The other objections, as to the multiplication of universities and the independence of the examiners from all undue influence of the teachers, are even more absurd. A complete answer is found in the case of the Victoria University. By the formation of this University, a great and almost unexampled impetus has been given to university work and higher education in the north of England, and we should expect similar good results to follow from the establishment of Universities on similar lines, one in London, and another in the Midlands. Teaching Universities would then be within the reach of our population in England, as they now are in Scotland and in Germany. In Victoria University, as shown by a recently published list, the most eminent professors and teachers in Great Britain are chosen as external examiners, and it is little less than an insult to insinuate that they are unduly biased by their local colleagues, as if true virtue could only exist within the walls of the London University. Even there, in the Faculty of Medicine, almost every examiner at the present time is a teacher in a metropolitan school of medicine, and must necessarily, to a certain extent, examine his own pupils. If these be the highest reasons that the Senate can bring forward for opposing the new movement, we cannot expect them to have much weight with Her Majesty's advisers.

Annotations.

"Ne quid nimis."

THE EMBANKMENT BUILDINGS.

A SUB-COMMITTEE, consisting of Mr. Marshall (chairman), Dr. Burdon Sanderson, Dr. Lauder Brunton, Dr. Ralfe, Sir Joseph Lister, and Mr. J. Hutchinson, have reported to the Colleges' Land Committee that the limitation in the extent of the ground at the back of the Examination Hall precluded the possibility of erecting buildings on plans similar to those adopted elsewhere. They therefore recommended that the original idea of two lateral blocks of four storeys, each containing four large rooms, with a theatre between them, should be adopted, with the erection of two galleries of rooms over the back part of the theatre from wing to wing, at a sufficient elevation to obtain a good south light. These galleries would provide eight rooms twenty feet long and fifteen feet broad, and the theatre could be made to accommodate 410 persons. The architect's approximate estimate for the construction of such buildings amounts to £26,000; and the sub-committee consider that an outlay not exceeding £5000 would be needed for internal fittings, the precise nature of which was postponed for future consideration. The report was adopted by the Committee, and will be submitted to the Colleges in due course.

COMPARATIVE MORTALITY IN ENGLAND AND IN AMERICA.

THE imperfect system of registration of vital statistics in America prevents the possibility of a useful comparison between the rates of mortality in England and in America. The rapid growth of life assurance in the United States has accumulated, however, a mass of statistics of mortality of still greater value for estimating the duration of life in that country than the results of any system of civil registration of births and deaths yet existing. During the thirteen years 1859-72, the number of life policies existing in the United States increased from 50,000 to 800,000. After 1872 the number of policies remained comparatively stationary for some years, but more recently the number has probably again increased rapidly. Fortunately for the present purpose—a comparison of the value of life in England and in America—a valuable series of experience tables, based on the life and mortality statistics of thirty American life assurance offices, was published a few years ago. The basis of experience upon which these American tables are constructed is sufficiently large to give the results a very definite value. The tables dealt with more than half a million of policies existing at the end of 1874, as well as nearly 50,000 previously lapsed by death, and nearly an equal number that had lapsed by surrender or discontinuance of premium—in all, with more than 600,000 policies, covering considerably more than 4,000,000 of years of life under observation. Among the more interesting results shown by these tables, it may be noted that the expectation of life of insured males in America at twenty years of age is 42·1 years, and exceeds by one year the expectation of males in England by the English experience tables; this excess in the male expectation of life in America is maintained through life, although it steadily decreases, until the advanced age of eighty-four, when the difference in favour of American life disappears. With regard to female life, the expectation of life at the age of twenty is precisely the same (40·8), both by the American and English experience tables; but afterwards, and until the age of forty-seven, the American expectation somewhat exceeds the expectation according to the English tables, while after the age of forty-seven the difference is

Digitized by Google

in favour of English life, increasing to a year at eighty years of age. One other marked feature disclosed by a comparison of these American and English experience tables is that in America expectation of life among insured females is lower than among insured males after the age of fifty-three years, while it is identical with that of males. It is well known that by all the principal English tables expectation of life among females exceeds that among males after the age of thirty-five years, and shows an increasing excess to the end of life. These differences between the expectation of life in America and in England relate, it should be remembered, solely to insured lives, mainly belonging to the middle and upper classes. If similar statistics were available for the general population, very much wider differences between the mean duration of life in America and in England would probably be shown.

ASSIMILATION OF FAT IN CATARRHAL JAUNDICE.

DR. P. A. VALTER, in a trial lecture recently delivered before the Conference (Senate) of the Military Medical Academy of St. Petersburg for the qualification of *privat-docent* or extra-mural teacher, dealt with the assimilation of fat in persons suffering from catarrhal jaundice. He detailed a number of observations and analyses he had made in several cases of this description, the results showing that the condition of catarrh of the bile ducts diminishes in a very marked degree the fat assimilated. It also produces a similar effect on the assimilation of the nitrogenous principles of the food ingested, but here the difference between the diseased and the healthy condition is not nearly so marked. He also found that when the patients were taking alkaline mineral waters the assimilation of fat was somewhat increased; the same was observed in the case of healthy persons. Thus, in a case of jaundice the percentage of fatty acids ingested which was found in the fæces, and therefore not assimilated, was 43·06 while taking the waters, and 45·95 when these had been left off, but after health had been re-established the percentage found was only 7·83. The percentage of nitrogen assimilated in a similar case was 88· while taking the waters, 77·4 after having left them off, and 91·7 after recovery of health. Dr. Valter described his observations, which were carried out in Professor Manassein's clinic, with great minuteness. The lecturer was accepted by the Senate as *privat-docent*.

MEDICINAL WARFARE.

BEFORE the first shock of the suggestion of dealing with excess of rabbits by cholera passes away, another idea reaches us which at first sight appears equally monstrous. An electrician, as quoted in the *United States Army and Navy Journal*, says: "It is well known that the nitrate (*sic*) of amyl possesses the power of causing insensibility very quickly in a human being breathing its fumes. The effect is equivalent temporarily to a paralytic stroke. Now, nitrate of amyl is very cheap and plentiful. I propose to fire shells filled with this chemical instead of gunpowder. It will not be necessary to penetrate a ship. A few gallons of this nitrate dashed on the deck of a war-ship would soon render her crew helpless. The most powerful ironclads would be even more vulnerable than the light cruisers, for they would be sucking down great draughts of air through their artificial ventilators, and the odour would thus rapidly permeate the whole ship. The whole crew being rendered helpless for an hour or two, the ship could of course be towed into a safe spot, while the captors ventilated her and removed the insensible men." This is indeed scientific warfare. Is all the fun to be on one side? What if the powerful ironclad attacked possessed similar shells? What becomes of the directions of the British Pharmacopœia about the cautious use of amyl? Is the whole suggestion based upon this, or is it a joke? The physiological effect of amyl is indisputable: the enemy, if sufficiently affected, would blush; and his arterial tension, and probably his esteem for his opponent, would be diminished.

FEVER IN LONDON.

THE continued diminution in the prevalence of scarlet fever is evidenced by the fact that only 158 cases of this disease were admitted into the hospitals of the Metropolitan Asylums Board during the week ending Dec. 16th. The number of patients discharged is now so much exceeding the admissions that a considerable amount of spare accommodation is at the disposal of the Managers; as yet, however, there is no reason for believing that this will be immediately required for any other disease. During the week under consideration enteric fever contributed 19 cases, typhus fever 2, and small-pox 2; both the typhus cases occurred in one house in Limehouse, the small-pox cases in Poplar and Mile-end. The Managers are making preparations for an accession of small-pox during next year, and have decided to provide a hospital for 728 convalescents from small-pox on the Gore Farm Estate at Darenth. The erection of this institution will, we presume, be undertaken forthwith.

THE MEDICAL JURISPRUDENCE OF INEBRIETY.

WE have received *proofs* of certain propositions which were laid before the New York Medico-Legal Society for discussion by their President, Dr. Clark Bell. In the synopsis before us we find the subject of inebriety arranged for forensic purposes under two heads—(*a*) civil obligation, and (*b*) criminal responsibility. As regards civil relations, it is noted that the definition of the fourth variety of *non compos mentis* of Lord Coke was that the individual of unsound mind was so "by his own act as a drunkard." After briefly touching on the question of delirium tremens, the author proceeds to show that when a person is wholly deprived of his reason by intoxication he cannot make a binding contract or act as a witness. It appears that the Supreme Court of every American State has in the matter of inebriety the same function which the Court of Chancery exercises in this country, but by legislative enactment the reference is made to different courts in certain States. Thus in New Jersey the Orphans' Court has the supervision whilst in South Carolina both the Common Law and Equity Courts can deal with the cases in question. "It will be observed that in many of the American States the *habitual drunkard* is classified and treated under the same provisions, and in the same manner as the lunatic and idiot." In New York, for example, it has been ruled that all contracts made by habitual drunkards, who have been so adjudged, are void, and that the civil disability continues after the committee has been appointed to supervise the estate and person, so that it remains binding even after the habitual drunkard has become perfectly sober, and fully aware of the nature and consequences of his acts. According to Dr. Clark Bell, the American law affords even greater protection still, for when a man has become so addicted to drink as to seriously interfere with the care of his estate, the court may step in and take absolute control of both person and estate. As regards criminal responsibility, we find there is little or no difference between the American and English law; both hold that drunkenness in itself is, *primâ facie*, to be considered as an aggravation rather than an extenuation of guilt—and rightly so, because, although a person may be so under the influence of drink as to be incapable of governing his acts, he is presumed when sober to have been able so to conduct himself as to avoid constructing a proximate cause of the commission of crime. The New York penal code lays

Digitized by Google

down that "no act committed by a person while in a state of intoxication shall be deemed less criminal by reason of his having been in such a condition; but whenever the actual existence of any particular purpose, motive, or intent, is a necessary element to constitute a particular species or degree of crime, the jury may take into consideration the fact that the accused was intoxicated at the time, in determining the purpose, motive, or intent with which he committed the act." This is sound law and common sense. This principle was acted upon last week in a trial at the Old Bailey, where a man was convicted of manslaughter, and not murder, for killing his wife when he was intoxicated. The motive in such a case must be considered rather as the impulse of a madman than the conscious purpose of a sober and sound individual.

ORGANISMS IN DYSENTERY AND HEPATIC ABSCESS.

IN the current number of the *Centralblatt f. Bacteriologie* Dr. Kartulis of Alexandria announces the interesting fact of the discovery within the pus of hepatic abscesses secondary to dysentery of the amœbæ which are constantly present in the dysenteric bowel. He had previously detected these amœbæ in the walls of such abscesses, but the case he now records is the first in which they were found in the contents. The case was a fatal one of abscesses in the liver and empyema supervening upon dysentery, from which the patient had suffered for three months. One of the abscesses was drained during life. The pus from this abscess and that of the empyema contained the amœbæ, but in the second intact abscess these animalcules abounded. They could be detected with low powers of the microscope as highly refractile bodies, which under high powers were seen to have active mobility. Their protoplasm was coarsely granular, but their nuclei and vacuoles were not very clear. Some of them contained within their substance red blood-corpuscles, which moved in the currents of the protoplasm. The amœbæ corresponded for the most part in size with those found in dysentery. Dr. Kartulis says that he has examined in all twenty cases of liver abscess, nine of idiopathic, and eleven of dysenteric origin. In the former the pus of only one case revealed any micrococci, but by cultivation the pus yielded the Staphylococcus pyogenes aureus in six cases. In all fatal cases in which the pyogenic membrane was examined micrococci were found within the capillaries bounding it. Of the eleven dysenteric cases, cultivations of the pus were made four times, yielding once the Bacillus pyogenes fœtidus and once the Staphylococcus pyogenes aureus. In eight cases examined post mortem the "dysentery amœba" was found in the detritus of the pyogenic membrane, as well as between the latter and the intact liver substance. In most of the cases colonies of micrococci, and in one bacilli, were found in the capillary vessels.

DRINKING IN NEW SOUTH WALES.

WE have lately remarked with pain on the drinking habits of some of our colonies, notably of New South Wales. A Royal Commission has been occupied for many months in taking evidence on this subject, and arrives at conclusions which should excite the concern of every inhabitant of the colony. The premier colony has the distinction of drinking more intoxicating drink, and that of a worse quality, than almost any other English-speaking community in the world. This is a bad distinction, which the following figures seem to confirm. The drink bill of the United States per head is £1 13*s.* 6*d.*, of New Zealand £3, of the United Kingdom £3 7*s.* 10*d.*, of Victoria £4 13*s.* 11*d.*, of New South Wales £5 14*s.*! In the city of Sydney alone there are said to be 3000 persons known to be habitual and absolutely hopeless drunkards. Dr. Maurice O'Connor, visiting surgeon of Durlinghurst Gaol, gave evidence that of 34,266 persons in six years and a half, 5685 were under actual medical treatment for diseases caused by drink. We are informed that not only does the colony drink more than other similar communities, but that it drinks much more than it did twenty years ago. The best symptom we read of is that the commissioners and the working classes are decidedly in favour of a restriction on the number of public-houses, and the entire prohibition of Sunday traffic. There is a law for Sunday closing, but it is shamefully evaded. One explanation for this sad state of things is perhaps the number of single colonists with little home life or comfort. But nothing can justify such drinking, or the community which, in the name of liberty, sanctions t. Ministers of religion and members of the medical profession should combine to amend a state of matters so fatal to health and morals.

THE LEICESTER AND LEICESTERSHIRE PROVIDENT DISPENSARY.

The *Leicester Daily Mercury* contains the report of a meeting of members of the above institution called to consider the management of it, under the presidency of the Rev. A. A. Isaacs. The President vindicated the right of members to criticise the management of the dispensary. The chief point of his complaint was that the manager received from the funds something near £1000—partly, as we gather, from salary, and partly from commission. He related that he had communicated with the chairman of the Board of Governors, Mr. W. H. Ellis, but seemed to get little approval from him of his complaints. Another grievance was that the members had no voice in the nomination of the Board of Governors, the subscribers only having the nomination in their hands. The financial facts brought out were that the expenses of the Society amounted to £2322 1*s.* 9*d.*, of which the members contributed £1246 18*s.* 5*d.*, leaving £1075 3*s.* 4*d.* to be provided by the subscribers. The year commenced with a balance due the treasurer of £986 18*s.*; it ended with a balance of £493. The complainants do not seem to have been very successful in carrying their resolutions. The manager's merits were vindicated by members of the Board of Governors. In the end a resolution was passed calling for a scrutiny of the accounts, and the meeting was adjourned. It would be interesting to know what proportion of the receipts fall to the lot of the medical staff and what work they have to do for what they receive.

WANT OF A SANITARY SYSTEM IN RUSSIA.

THE Vice-Director of the Russian Medical Department, Dr. Bubnoff, has recently issued a report on Sanitation in Russia, in which he remarks that no working sanitary system can be said to exist in the empire. This is, indeed, only too true, as all the reports which pass into the archives of the Medical Department must impress on the minds of those who, like Dr. Bubnoff, are responsible for the sanitary condition of Russia. The death-rate in some districts ranges from 60 to 80 per 1000, of which an enormous proportion is due to mortality amongst children—in some places, indeed, as much as 79 per cent. of the total mortality. In spite of a high birth-rate, the population is increasing only at the rate of 1 per cent. Every year some 2,800,000 persons die in Russia. According to Dr. Bubnoff's statistics, something like 1,000,000 of these deaths may fairly be traced to preventable causes. There is a great paucity of medical men, of whom there are only about 5000 altogether for 100,000,000 inhabitants, and these of course tend to congregate in the towns, so that in rural districts doctors are to be met with only at long intervals.

LOBAR ARRANGEMENT OF PHTHISICAL LESIONS.

AN examination of the literature of pulmonary phthisis will show how little attention has been paid by most writers to the question of the exact distribution of the lesions in the lungs and their relation to the chest wall. Dr. Kingston Fowler has gathered together some facts of importance, and in the *Practitioner* gives us the outcome of his own experience. He believes that there is a definite mode of extension of the lesions of phthisis through the lungs, and has found great assistance in the diagnosis and valuable aid in the prognosis from a recognition of this fact. We agree with Dr. Fowler in thinking that there probably is in most cases of phthisis a distinct "line of march." The extreme apex of the lung is not often the site of the primary lesion; it is situated from an inch to an inch and a half below the top, and rather nearer to the posterior and external borders. Lesions in this region tend to spread in the first instance backwards, possibly from inhalation of the virus whilst the patient is lying down. This accounts for the fact that an examination of the supra-spinous fossa will often give certain evidence of the presence of disease when the physical signs in front of the chest have left some doubt. From this primary focus, which in front corresponds either to the supra-clavicular fossa or to a spot immediately below the centre of the clavicle, the lesions often first spread downwards along the anterior aspect of the upper lobe, about three-fourths of an inch within its margin, frequently occurring in scattered nodules, separated by an inch or more of healthy tissue. The second and less usual site of the primary affection of the apex corresponds on the chest wall with the first and second interspaces below the outer third of the clavicle. The lines of extension are usually downwards and backwards. The lower lobe of the lung primarily diseased is usually affected at a very early period. The site of the primary infiltration of the lower lobe is generally situated about an inch below the upper and posterior extremity of the apex of the lower lobe, and this situation corresponds on the chest wall to a spot opposite the fifth dorsal spine midway between the border of the scapula and the spinous processes.

THE PROGRESS OF BOTANY IN CALCUTTA.

SURGEON-MAJOR G. KING, the Superintendent of the Royal Botanic Garden, Calcutta, has recently presented his annual report to the Secretary to the Government of Bengal. This being the hundredth annual report, he has deemed it a fitting opportunity for giving a brief history of the Garden. Founded under the advice and guidance of Colonel Robert Kyd, it originally comprised a large collection of exotic plants, chiefly from the Straits. Subsequent superintendents enlarged the original scheme of the work, and did much to further the systematic study of the plants of India. Collecting expeditions were organised, and a botanical survey of a large part of the Indian Empire was undertaken. It was originally intended that the Garden should be a source of botanical information, and a centre to which exotic plants of economic interest could be imported for experimental cultivation, and from which in turn they could be issued for distribution. It was also intended to assist in introducing indigenous Indian products to new markets, and to be not only a botanical, but also a horticultural and agricultural garden. In early days the Garden undoubtedly did service of a negative nature by demonstrating that certain desirable natural products cannot be grown in Bengal. Later the Garden bore an important part in the final establishment of the tea industry in Northern India, and also in initiating and carrying to a successful issue the cultivation of the quinine-yielding cinchonas of the Andes. Under the present superintendent much has been done to repair the ravages of cyclones in 1864 and 1867, new roads and footpaths have been made, and three new conservatories have been erected. The interchange and distribution of plants and seeds have gone on actively during the year; 8064 plants have been received, and 46,104 issued; 933 packets of seeds have been received, and 2534 packets have been distributed. The report shows very clearly the valuable character of the work carried on at the Botanic Garden, Calcutta. It is certainly desirable that such authoritative help should be given to check the needless waste of individual efforts.

ACTION TO EXTORT MONEY FROM MEDICAL MEN.

WE publish in another column an oft-told story of the risks run by medical practitioners daily in the discharge of their duties. The repetition of the publication of such cases seems needless and *ad nauseam*. But, in truth, it is only by their publication that the evils attendant on them can be exposed or arrested, and that the *moral* they convey can be sufficiently impressed on busy practitioners. Men in the midst of a day's work, and called on, perhaps unexpectedly, to consider whether a servant has typhoid or constipation, are apt to forget the amenities of procedure. There is not a day in any busy practitioner's life in which he is not almost inevitably thrown into circumstances out of which a prurient or malicious mind might construct a plot and a case for his discredit or ruin. This is no reason, however, why he should not act with excess of caution. The case we publish in full elsewhere bristles with lessons. In our profession we need "to be wise as serpents and harmless as doves." The evidence of Mr. Gittings' high character does not permit any doubt as to the propriety of the judgment against his accusers, save for its excessive leniency. But we must not the less insist that he would have exercised a just discretion in leaving the exact diagnosis of the servant's case till he could confer with her mistress. We regard his case as one for the sympathy of the profession, and as illustrating how badly we are in want of an efficient means of medical defence.

THE MICROBE OF SYPHILIS.

DR. J. DISSE, Professor of Pathological Anatomy, and Mr. K. Takaki, Professor of Normal Anatomy, in the Tokio University, Japan, publish in the first number of the Reports of the Medical Faculty an account of a series of experimental researches, on which they have been engaged for some time, dealing with the nature of the syphilitic virus. They examined chiefly the blood of syphilitic persons, especially of such as had been cured of all manifestations of the disease. They selected the skin of the face on account of its great vascularity, of course cleaning it very carefully with antiseptics before making the necessary puncture. In most of the cases spherical bodies, nearly 0·001 mm. in diameter, which could be stained by Gram's method, were found; these occurred singly or in groups between the blood-corpuscles. They were not easy to be distinguished unless the layer of blood was extremly thin. A magnifying power of 350 diameters was used, an oil-immersion lens and a good illumination being indispensable. They were, the writers believe, invested with an envelope. In non-syphilitic subjects, whose blood was examined with similar precautions, these bodies could not be found. From blood containing these organisms cultures were prepared, various media being employed. Of the cultures attempted about three-fourths were successful. Of course, extraneous organisms made their appearance, but with care pure cultures were obtained. When they were examined microscopically, there were found—1. Simple spherical forms, having a diameter of 0·0008 mm. 2. Double spheres, looking

Digitized by Google

like short rods with rounded ends; the length of these was 0·0018, and the breadth rather less than half the length. 3. Chains and groups really formed of the double spheres. 4. Occasionally three spheres in line, measuring 0·0027 mm. All these forms were invested with envelopes which did not take the stain, and therefore were difficult to distinguish. In one culture an ovoid bacterium with a clear spot in the centre was found on the third day, but subsequently this had apparently changed into the ordinary form. The double spheres, or diplococci, as they evidently were, were found to have a movement decidedly greater than non-pathogenic cocci, with which they were compared. The single cocci had no movement, and did not multiply. The diplococci were seen in the process of multiplication, which was accomplished as follows: the two cocci separated quickly, and immediately afterwards each divided into two, which did not part company, but remained joined together, forming a new diplococcus. It was evident that the diplococcus must be the perfect individual, as it presented the phenomena of movement, growth, and multiplication. The single cocci without movement were considered to be arthrospores, and these were the only pathogenic organisms found in the blood in latent syphilis. Cultures of these arthrospores from the blood of syphilitic subjects, which consisted mainly of diplococci, were used to inoculate animals, and produced in them changes which, though not identical with the morbid changes generally found in human syphilitic subjects, bore so close a relation to them that there was little doubt that the disease was really syphilis. Hereditary syphilis was also produced, as evidenced by the examination of the placentæ and of the fœtal offspring of animals which had been inoculated. In a week's time after the inoculation the organisms could be detected in the animals' blood. Should these researches be confirmed, the discovery is of great importance; but it is as well to point out that hitherto the ape has been the only animal in which successful inoculations have been alleged to be successful (Klebs), and even in these cases the evidence that the caseous foci produced were syphilitic and not tubercular is incomplete; whilst as to micro-organisms, which have from time to time been found in syphilis, none, except those which were obviously due to septic contamination (see THE LANCET, vol. ii. 1887, p. 771), coincide with those above described, and Lustgarten's bacillus is of quite a different class.

TRADE USES OF PROFESSIONAL NAMES.

DR. JOHN WILLIAMS deserves the thanks of the profession for his attempt in the High Court of Justice to restrain a firm of surgical instrument makers from using in their trade catalogue Dr. Williams's name as the inventor of a certain vaginal syringe. It would be thought that a respectable firm would not lightly use the name of a distinguished practitioner in a common advertisement, or, at least, that on being remonstrated with for doing so they would immediately apologise and desist. This they actually refused to do, and Dr. Williams had no remedy but the costly one of law. Unfortunately this proved a broken reed. The judge admitted that Dr. Williams's request was reasonable. He even went the length of saying that the defendant had no more right to use the name of the plaintiff than to take his purse. But he did not grant an injunction. He would have done so had he been dealing with the case as a *res nova*. But he was hindered by a surprising judgment to the contrary effect in the case of Clark *v.* Freeman, in which the name of Sir James Clark was used to set off a pill which he had never heard of, and which he would never have dreamt of telling his patient to take. In that case Lord Langdale refused the injunction. This was "surprising" indeed, as the judge said. Only one thing is more so to the lay mind—that Mr. Justice Kay should have felt bound by a judgment so contrary to justice, common sense, and the interest of the public. Dr. Williams has done what he could, and no one who knows him would doubt his perfect disgust with such methods of business.

PROFESSOR LANKESTER AND THE UNIVERSITY OF OXFORD.

PROFESSOR LANKESTER has obtained a mandamus to compel the authorities of the University of Oxford to hear his defence against his dismissal from the office of examiner in Animal Morphology in June last. It would appear that Professor Lankester conducted a practical examination as well as a written one on the same day, instead of holding a written examination on one day and a *viva voce* examination on two other days, as fixed by the authorities of the University. Consequently the Vice-Chancellor summarily dismissed him. Doubtless the conditions of the examination as laid down by the authorities are obsolete, and require to be altered on more modern lines.

EXTENSION OF SMALL-POX.

SMALL-POX is still extending, especially in South Yorkshire and in the northern part of Derbyshire. The outbreak in Leeds has assumed large proportions, and it is stated that some of its diffusion is through common lodging-houses tenanted by tramps from Sheffield. The Town Council of the latter place have decided that they cannot wait for formal official inquiry and sanction, and that they must, in view of the emergency, proceed with their new small-pox hospital without the approval of the Local Government Board. We hope that sanitary authorities generally will turn their attention to this subject of small-pox isolation, before they find themselves confronted with an occurrence of this disease; for unless arrangements beyond those needed for the other current infectious fevers are decided on in advance, public bodies may find themselves beset with difficulties and opposition, that are almost certain to increase year by year.

THE COMMA BACILLUS IN NEW YORK.

IN the *New York Daily Tribune* of Nov. 27th there is a short leader setting forth that pathognomonic importance is attached to the comma bacillus by some authorities in New York. The arrival of an Italian steamer with a suspicious case resembling cholera embarrassed the medical officers of health. The Carnegie laboratory was put to its proper use. The comma bacillus was discovered, and the diagnosis of cholera was delivered with confidence. The steamer was ordered to remain in quarantine, and other preventive measures were used. A second case occurred in New York, in which the symptoms were like those of true Asiatic cholera. But a careful search for the bacillus proved unsuccessful, and the case was soon well. We are not quite so sure in this country of the value of the comma bacillus as they seem to be in New York.

A CURIOUS VERDICT.

AN inquest was recently held at Little Ilford before Mr. C. C. Lewis, touching the death of Elijah Cook, aged forty-seven. The deceased was a grave-digger at Manor-park Cemetery. He was found dead in bed. The jury found a verdict of "Death from disease, the precise nature of which was not known, but probably from heart disease." We are informed that no medical evidence was called. If this was the case, we do not hesitate to say the judicial ceremony was singularly faulty. Surely a doctor is the person best

Digitized by Google

qualified to assist a coroner's jury in arriving at the truth as to the cause of death. If professional testimony had been adduced to the effect that the deceased had suffered from cardiac trouble, and the other facts were consistent with the supposition that death arose from syncope, we see no reason why a post-mortem examination should have been made. On the other hand, where more than reasonable doubt exists as to antecedent disease, and as the actual cause of death must be to a great extent problematical in the case of a person found dead, it would be far more satisfactory for the coroner to order the fullest investigation.

THE LATE ARTHUR FARRE, M.D.

WE regret to record the death, on the 17th inst., of Arthur Farre, M.D., F.R.S., Physician Extraordinary to the Queen. Born in 1811, Dr. Farre received his early education at the Charterhouse, and then proceeded to Caius College, Cambridge. He received his professional education at St. Bartholomew's Hospital, and took the M.B. degree at Cambridge in 1833, and that of M.D. in 1841. Becoming a Member of the Royal College of Physicians in 1838, Dr. Farre was elected a Fellow in 1843. He was lecturer on Comparative Anatomy at St. Bartholomew's Hospital in 1836 and 1837, and on Forensic Medicine from 1838 to 1840 inclusive. For the long period of twenty-two years—viz., from 1841 to 1862—Dr. Farre was Professor of Obstetric Medicine at King's College and Physician-Accoucheur to King's College Hospital, being appointed Consulting Physician to that institution in 1863. He acted as Censor, Examiner, and Councillor in the Royal College of Physicians, and was appointed Harveian Orator in 1872. For twenty-four years he was Examiner in Midwifery in the Royal College of Surgeons. In addition to being Physician Extraordinary to Her Majesty, Dr. Farre was Physician-Accoucheur to the Princess of Wales, the Duchess of Edinburgh, the Princess Christian of Schleswig-Holstein (Princess Helena of Great Britain), and the Princess of Leiningen. He also attended the lamented Princess Alice of Hesse Darmstadt in her first confinement.

EFFECTS OF PHOSPHORUS ON YOUNG ANIMALS.

DR. ALEXANDER KISEL of St. Petersbnrg, who has made a series of observations on the effect of small doses of phosphorus on young animals, has found that it never exerts any beneficial effect on the growth of bone, but that, on the other hand, the apparently slight disorder of the digestive functions which very small doses produce is liable to result in death. When given to puppies in doses of 0·0001 gramme per kilogramme of weight, symptoms of chronic poisoning were produced, with atrophy and disintegration of the bones. In doses of half this amount the development of the animal was retarded, but those equal to 0·000023 gramme per kilogramme of weight appeared to be innocuous and produced no effect at all upon the body.

THE DECLINE OF CHINESE TEA.

THE decreased consumption of Chinese tea in the English market has been ascribed to deterioration in the quality of the leaf, excessive admixture of dust, and the like. But it would seem probable that the deterioration is apparent rather than real—that it is owing to the improvement of the scientific methods adopted in India, while those in China have been in vogue for centuries. The products of the highly organised plantation system of India, with its effective and rapid treatment by machinery, must naturally beat those of the small Chinese farmer, who cultivates an acre or so, and sells the leaf to an itinerant purchaser, who keeps it till he has collected enough to make it worth his while to fire it, when it has lost much of its flavour. In this connexion, however, it must not be forgotten that other causes will influence the market. In the United States the consumption of tea has in recent years materially decreased, whilst that of coffee has undergone an almost corresponding increase.

REFUSAL OF THE BELGIAN GOVERNMENT TO LICENSE FOREIGNERS TO PRACTISE.

IT having been rumoured in Belgian professional circles that the Government were about to give licences to practise to a considerable number of foreign medical men without subjecting them to any examination, the Belgian Medical Federation asked Dr. Thiriar, the well-known Brussels surgeon, who is also a member of Parliament, to communicate with the Minister of the Interior and of Public Instruction, M. de Volder, on the subject. To this communication a reply was received, stating that he had made up his mind to abstain entirely in future from giving authorisations to practise to foreign medical men. A Bill is now before the Chambers dealing with this and other medical matters, and when this is passed it is probable that the power to give licences to practise will no longer remain with the Minister of the day.

TOXICITY OF PULMONARY EXHALATIONS.

DOES the surface lining of the lungs give off a toxic substance like the general run of glandular surfaces? MM. Brown-Séquard and d'Arsonval reply to this question in the affirmative and as the result of direct experiments performed on rabbits. If a certain quantity of water be injected into the lungs of an animal and then be immediately withdrawn, and after filtration injected into another animal, phenomena of poisoning are observed. A considerable diminution in the breathing is the chief observation, and this is attended with dilatation of the pupils. The animal died in seven hours. At the necropsy cerebral anæmia was noted, and serous effusion into the ventricles and at the base of the brain. There were no signs of embolism; the heart was contracted and the cavities on both sides contained black blood; the blood was red in the inferior vena cava, but black in the superior. Expired air contains something more than gas and water—a fact which needs in itself no further attestation than that supplied by the olfactory sense.

OCULAR SYMPTOMS OF EPILEPSY.

THE examination of a thousand cases of epilepsy by Dr. Gowers revealed but one morbid condition of frequent occurrence in the ocular fundus, and that was an unnatural equality of the size of the arteries and veins of the retina. Dr. Charles Oliver of Philadelphia has frequently observed a reduction of the visual fields for form and colour, a granular condition of the choroid in the macular region, a dirty red-grey degeneration of the optic nerve, and a thickening of the fibrous tissue of the retina.

THE PUBLIC VACCINATOR FOR CARDIFF.

THE public vaccinator for Cardiff has been deprived of his appointment on grounds which cannot be clearly understood from the account given in a local journal of the proceedings of the Cardiff guardians. The Vaccination Committee had expressed their disapproval of the conduct of this officer, who on the recent occasion of an outbreak of small-pox at Pentyrch was applied to for a supply of lymph by the medical officer of health and public vaccinator for the Pentyrch district; but the nature of this conduct, which is thus severely dealt with, does not appear. The public

Digitized by Google

vaccinator for Cardiff has held this office for over ten years, and has, we believe, always received the grant of the Local Government Board. The circumstances therefore which could justify the termination of his contract ought to be proved to be sufficient to justify so grave a step, and we hold very strongly should be made the subject of inquiry.

KING'S COLLEGE.

THE death of Professor Bloxam has caused the following changes to be made in the Chemical Department:—J. M. Thomson, F.R.S.E., has been appointed Professor of Chemistry; G. S. Johnson, F.C.S., has become Senior Demonstrator, and H. Jackson, F.C.S., Junior Demonstrator. In the Hospital, Mr. Ashley Gibbings, M.R.C.S., L.D.S., has been appointed Professor of Dental Surgery and Dental Surgeon, in place of Mr. Hamilton Cartwright.

MENINGEAL HÆMORRHAGE.

A FEMALE patient, aged twenty-six, was admitted under the care of Mr. Croft, in St. Thomas's Hospital, about midnight on Dec. 11th, in a semi-comatose condition. She was supposed to have been knocked down and kicked by a horse. There was a scalp wound, not leading down to bone, behind and below the left parietal eminence. There was no evidence of fracture. During the night she passed into a state of absolute coma, and in the morning had complete paralysis of the right arm and leg, but not of the face. Mr. Croft trephined in the situation of the wound, removing about two ounces and a half of somewhat granular clot, which was spread out for some distance between the dura mater and the bone. The hæmorrhage was from some vessels in the dura mater (probably posterior branches of the middle meningeal), and could only be arrested by means of pressure. About six hours later the power of movement returned in the right side, and her condition gradually improved. She spoke for the first time after the injury on the 13th. Although not yet recovered, she is still restless at times, and impatient of control; there is no paralysis, the wound is quite aseptic and healing, and the improvement continuous. A severe contusion of the groin was, however, followed by sloughing and cellulitis, for which incisions were required.

THE SANITARY STATE OF SHIRLEY.

AT a lengthened meeting of the Croydon Corporation the question of the ventilation of the Shirley sewers was again discussed. It was announced that the high shaft ventilators which have been so long in coming may be expected to be in position within about a week; but on behalf of the Shirley people it was contended that this did not satisfy them. Their demand is that the existing ventilators on the road level shall be closed, and that the high shafts shall alone serve as ventilators. On the other hand, it was pressed that since the Local Government Board had only recommended that the high shaft ventilators should serve as an additional means of ventilation, the experiment of the duplicate system ought at least to be tried for a time. This proposal was much opposed by those who professed to represent the wishes of the inhabitants of the hamlet of Shirley, but in the end a large majority decided that the road man-holes should remain open.

DEATHS OF EMINENT FOREIGN MEDICAL AND SCIENTIFIC MEN.

THE deaths of the following foreign medical and scientific men are announced:—Dr. Mehu of Madrid, author of several important works on Pharmaceutical Chemistry.—Dr. Enrique Madrazo, editor of *El Correo Médico Castellano*.—Dr. V. V. Glovachevski of Irkutsk, well known for his writings on Diseases of Children.

H.I.H. THE CROWN PRINCE OF GERMANY.

THE latest intelligence concerning the condition of H.I.H. the Crown Prince is of a satisfactory character. At the end of last week, as we learn from San Remo, a small nodule became evident in the middle of the left ventricular band, which was slightly swollen throughout. This excrescence increased, and was then about the size of a split pea. It was not strictly defined, but its base passed insensibly into the surrounding tissues. It looked more like a "false excrescence," such as Mackenzie has described in his work on "Growths in the Larynx," than a true growth. The former growth (of end of October) was considerably smaller, and had a cicatrix on its surface. There was no œdema. The submaxillary glands were absolutely normal in size, and the general health was perfect.

THE GASTRIC JUICE AFFECTED BY SLEEP.

DR. P. V. BURJINSKI, of Professor Manassein's Clinic in St. Petersburg, having enlisted the services in the cause of science of some students and other persons who managed to overcome the natural repugnance most people feel to the passage of even a soft œsophageal tube, has made some investigations on the effect of sleep upon the acidity of the gastric juice. He estimated this acidity by means of a standard solution of soda, and he tested it also for hydrochloric acid. The best test for the latter he found to be floroglucin-vanillin. As, however, this cannot be used when there is any yellow colour in the fluid to be tested, the subjects of the experiments were fed on the whites of eggs, all the yolks being carefully put aside. The result of numerous tests showed that during the night the gastric juice is less acid than during the day. Care was of course taken that the conditions regarding food were the same during the night as during the day. Dr. Burjinski also found that the amount of acidity varied directly with the amount of hydrochloric acid present.

NUISANCE FROM METROPOLITAN REFUSE.

IN a special report on the storage, collection, and conveyance of offensive substances through the streets, Dr. Dudfield points out a very prominent evil in London administration. The refuse of dustbins is conveyed through the streets in open vehicles in such a way as to allow it to blow about in people's faces; and bones, skins, and other decomposing materials are similarly carted about with the result of producing offensiveness and nuisance. Any small country town can make bye-laws to regulate such matters by adopting the model clauses issued by the Local Government Board dealing with the prevention of nuisances arising from filth, dust, ashes, rubbish, &c., but London appears as yet to be unable to control the evil. As Dr. Dudfield well puts it, all refuse matters, whether the result of trades or of ordinary housekeeping, should be stored in impermeable covered receptacles and removed frequently, and without nuisance or annoyance, in properly constructed covered vehicles.

QUININE v. OPIUM.

MR. JOHN FERGUSON, a resident of Ceylon, has drawn attention to the wide-spread use of opium in malarial districts, and he ascribes the opium craving in such places to a low type of fever. He believes that sulphate of quinine, and even the other alkaloids from cinchona bark, counteract the ill effects resulting, and his suggestion is that quinine removes the craving and acts as a substitute for laudanum. This explanation is obviously insufficient. Quinine evidently combats the malarial influence, and thus removes the low state of depression which favours the opium habit, into which the unfortunate people gradually glide in the attempt

Digitized by Google

to forget their physical condition. In this way only does it appear probable that quinine acts in superseding the need for opium, its action being tonic and prophylactic rather than antidotal. Mr. Ferguson usefully points out that the retail prices have not fallen proportionally to the great reduction in the wholesale prices.

TETANUS.

ACCORDING to MM. Nocard and Brieger, tetanus is a disease transmitted to men and animals by the agency of a pathogenic organism which infects wounds or other suitable soils on the surface of the body. The organism does not penetrate far beyond the limits of its point of inoculation, but exercises its deleterious influence by means of certain products of an alkaloidal nature, and of which there are, according to Brieger, four kinds—tetanin, tetano-toxine, spasmo-toxine, and another not named. The alkaloids have a special affinity for certain parts of the motor nervous system, causing excessive discharges of nervous energy, on which the muscular spasms are directly dependent. M. Nocard found that dried blood and pus scraped from instruments which had been used to geld horses (all of which died of tetanus), when inoculated beneath the skin of rabbits and guinea-pigs, caused tetanus; and yet infusions made from the medulla oblongata and spinal cord of animals dead from tetanus were not capable of causing tetanus in other animals into whom some of the infusion was injected. The argument is not free from fallacy, but the conclusion drawn is that the spinal cord and medulla are acted upon by a strychnine-like substance, of course incapable of cultivation, but derived from the multiplication and growth of organisms elsewhere existing.

MENTAL DISORDER CAUSED BY JABORANDI.

DR. WAUZH of Liège, who has great belief in the efficacy of jaborandi as a stimulant of the mammary functions, mentions a case which has recently occurred in his practice, showing that inconveniences may occasionally arise from the administration of this drug. He prescribed ten drops of the fluid extract every four hours for a patient whose milk had ceased for a fortnight, with satisfactory results, the secretion being re-established. After a time, however, the patient began to suffer from extreme nervous excitement, accompanied by a fixed idea that she should murder all her family with a hatchet. On the jaborandi being stopped these alarming symptoms disappeared, and together with them the activity of the mammary glands.

FOREIGN UNIVERSITY INTELLIGENCE.

Buda-Pesth.—The names mentioned for the Chair of Special Pathology and Therapeutics are very numerous, the best known being Dr. Jendrassik, *docent* in the University, and Professor Bókai of Clausenburg.

Marburg.—Professor Braun of Jena has been appointed to the Professorship of Surgery. He will commence his duties after Easter.

Würzburg.—Professor Scanzoni, the well-known obstetrician, is about to retire on a pension at the age of sixty-seven.

AMONG those who were ordained Priest by the Bishop of Rochester on Sunday last occurs the name of the Rev. J. E. Hine, B.A. Oxon. and M.D. Lond., formerly Fellowes Gold Medallist and Atchison Scholar of University College Hospital, and late house-surgeon of the Radcliffe Infirmary, Oxford. We understand that Dr. Hine intends before long to join the University's mission to Central Africa as a medical missionary under Bishop Smithies.

SAVE on the occurrence of exceptional floods, the variations in the character of the river water supplied to London are, for the most part, very limited in range. Within the range, however, some variation usually makes itself manifest with the approach of the month of November, and accordingly, as appears from Messrs. Crookes, Odling, and Tidy's report, a slight variation in the composition and character of the water, as prevailing with great uniformity during the previous four months, was recognisable in last month's supply. Thus the mean proportion of organic carbon in the Thames-derived supply was found to be ·145 part, with a maximum in any one sample examined of ·166 part in 100,000 parts of the water, as against a mean of ·137 part and a maximum of ·169 part in the preceding four months' supply—the variation, it is observable, being very insignificant.

THE death is announced of Professor Balfour Stewart, M.A., LL.D., F.R.S. The deceased, who had only just completed his fifty-ninth year, was educated at the Universities of St. Andrews and Edinburgh. In 1859 he was appointed to the directorship of the Kew Observatory, and in 1867 to the secretaryship of the Meteorological Committee, which last appointment he resigned on his promotion to the professor's chair of Natural Philosophy in Owens College in 1870, a post which he held until his death. In 1868 he was awarded the Rumford Medal by the Royal Society, for his discovery of the law of equality between the absorptive and radiative powers of bodies.

IN the list of successful candidates at the recent examination for the degree of M.D. at the London University appears the name of Mr. K. N. Bahdurji, a Parsi gentleman of Bombay. He is the first Parsi to gain this degree, and the second native of India, the first being the late Dr. Chukerbutty, who passed in 1845.

PROFESSOR WILLIAM ROBERTSON, the Principal of the Royal Veterinary College at Camden Town, expired suddenly a few days ago whilst correcting proofs of a work he had written on Veterinary Surgery. The deceased was fifty-seven years of age.

SENOR CALLEJA, the Spanish Director of Public Instruction having retired, this important post has been filled by the appointment of Señor Nieto, son of Señor Nieto Serrano, Director of *El Siglo Médico*, the leading Spanish medical journal.

AT a meeting of the committee for the election of officers on the 19th inst., Dr. Arthur Gamgee, F.R.C.P. Edin., F.R.S., was elected an assistant physician, and Mr. George R. Turner, F.R.C.S., an assistant surgeon to St. George's Hospital.

THE Lettsomian Lectures will be delivered at the Medical Society of London by Mr. Reginald Harrison, on Jan. 2nd, 16th, and 30th, 1888. The subject will be "On some Points in the Surgery of the Urinary Organs."

DR. PESET CERVERA and Dr. Tuñon y Lara have been appointed Directors of the Laboratories of Forensic Medicine in Madrid and Barcelona respectively.

HOSPITAL SATURDAY FUND.—The report of the Distribution Committee of this fund was adopted at a meeting of the delegates held at the board-room on Wednesday last, which recommends that £10,000 of the £11,300 collected be distributed among 76 hospitals, 39 dispensaries, and 23 convalescent homes and other institutions. The awards to the hospitals amount to £6868 1*s.* 2*d.*, the dispensaries receive £853 6*s.*, and the convalescent homes £1340 10*s.*

Pharmacology and Therapeutics.

HYPODERMIC INJECTIONS OF ANTIPYRIN.

Two papers have just appeared on the value of subcutaneous injections of antipyrin for the relief of pain, as recommended by Professor Germain Sée—one by Dr. Hirsch of Hanover, the other by Dr. Capitan of Paris. Dr. Hirsch uses a solution made of equal weights of antipyrin and distilled water—(i.e., a 50 per cent. solution by weight). Of this he injects a Pravaz-syringeful (fifteen minims) into the painful spot, and in this way he has obtained most marked success in cases of neuralgia of the fifth, sciatica, and both muscular and articular rheumatism, some of them of long standing. In some instances the relief was both instantaneous and permanent. He advises that the syringe should after use be very carefully washed out with a 5 per cent. carbolic solution in order to prevent the lumen of the needle being stopped up by particles of antipyrin. Dr. Capitan, whose valuable paper in the *Bulletin Médical* is partly a *résumé* of the previous observations of various physicians, including a good deal of matter contained in a graduation thesis by Dr. Caravias, states that the solution of antipyrin in its own weight of water, though it may be used hypodermically, is painful, and he therefore adds fifteen parts of cocaine for every 1000 parts of antipyrin. With this solution the injection is much less painful than when no cocaine is added. The place where the needle has penetrated usually becomes slightly raised and tender, and once or twice small abscesses have formed. The usual dose employed by him is thirty minims. In dysmenorrhœa, and uterine pain generally, an enema (which is to be retained by the patient) of warm water containing seventy-five grains of antipyrin gives the best results. The action of this drug in relieving pain of very diverse kinds of origin—e.g., neuralgic, rheumatic, herpetic, &c.,—whether given by the mouth, by the bowel, or hypodermically, is very strongly praised by Dr. Capitan, who suggests that every medical man can easily verify its remarkable anodyne power by a few simple trials. The doses he recommends are somewhat higher than those frequently given; thus he puts the dose for internal use at from thirty to ninety grains, and that for hypodermic use at from fifteen to sixty grains.

STROPHANTHUS.

Some practitioners have looked with displeasure on strophanthus—the remedy so much vaunted of late as of value in heart disease. It can hardly be that the valvular lesions in different cases required a different remedy to act upon the heart muscle, unless, indeed, our present physiology is altogether wrong, and the doubt therefore arises whether the strophanthus itself is free from blame. Some false varieties of strophanthus are said to have been put upon the market, and some of the genuine strophanthus hispidus has been deteriorated by decomposition and by invasion with fungus, or immature seeds have been supplied. Such conditions must needs bring disrepute, and it behoves us to guard against them by obtaining the drug from perfectly reliable sources. Dr. John Aulde, of Philadelphia, has a paper in the *Medical and Surgical Reporter*, No. 2, vol. lvii., in which he speaks of the value of strophanthus not only as a cardiac tonic, but also as a direct diuretic, by increasing the activity of the vascular system. In cases of fever where there is great tension, with a hot and dry skin, scanty and high-coloured urine, he remarks, with truth, it is surprising how quickly we observe the diuretic action of a small dose of aconite frequently repeated. Aconite is regarded not only as increasing the secretion of the watery parts of the urine, but also of the solid parts. But while aconite reduces, digitalis increases tension, showing that strophanthus may be substituted for digitalis as a diuretic when it is desired to avoid increased blood pressure. It is suggested that this effect may be explained by assuming that in such cases there is too much tension, and that, this condition being relieved, compensation is re-established when cellular activity begins. In ordinary cases of cardiac dilatation, or in those cases dependent on typhoid fever and pneumonia in which alcoholic stimulants are indicated, strophanthus is recommended; and also in patients in the later months of pregnancy who suffer from a flabby condition of the cardiac muscle along with œdema of the lower extremities. But Dr. Aulde would not say that the presence of albumen in the urine would not be a contra-indication to the use of strophanthus. He also thinks that the drug may be used in preventing collapse during the production of anæsthesia, and as a remedy to prevent the depressing effects following the use of chloral and bromide.

GUAIACOL AS A SUBSTITUTE FOR CREASOTE IN PHTHISIS.

DR. H. SAHLI of Berne, writing on the treatment of phthisis by creasote, remarks that creasote, by which is meant that prepared from the tar obtained by the destructive distillation of beech wood, is a complex substance, the constituents of which vary considerably in different samples, and that it is surely desirable to use for therapeutical purposes some simple substance of known composition. He finds that in the beech creasote, as prescribed in the Swiss Pharmacopœia, the largest constituent is guaiacol, the methyl-ether of pyro-catechin, $OH.C_6H_4.OCH_3$, which constitutes from 60 to 90 per cent. of the whole, the rest being chiefly made up of creasol, the mono-methyl-ether of homo-pyro-catechin, $OH.C_6H_3[CH_3].OCH_3$. Guaiacol being the chief constituent of creasote, Dr. Sahli prescribed it in cases of phthisis, and found that it had an excellent effect in moderating the cough, making expectoration easier, frequently diminishing the secretion, and improving the patients' appetite and general condition. Some who were confined to bed and suffering from a considerable degree of pyrexia were unable to retain the medicine, and vomited it. In some cases, too, it brought on diarrhœa. On the whole, however, Dr. Sahli was well satisfied with the guaiacol as a substitute for creasote. It is a colourless highly refracting liquid, soluble in alcohol, ether, and fat oils, but only slightly so in water. The alcoholic solution gives with perchloride of iron an emerald-green colouration. The taste and odour of guaiacol are more agreeable than those of creasote. As solutions of guaiacol deposit resinous substances when exposed to light, they should be kept in coloured glass bottles. One or two parts of guaiacol may be dissolved in 180 parts of water and 20 of spirit. One or two teaspoonfuls of this may be ordered in a glass of water two or three times a day after meals, or the guaiacol may be dissolved in cod-liver oil, which almost completely disguises its smell. In this way larger doses can be taken than when the solution in water is prescribed. The price of guaiacol does not seem to be very much higher than that of creasote.

SENEGIN.

Polygala senega and Polygala boykinii—i.e., the northern and southern varieties of senega-root—contain, according to Dr. Joseph Atlass of Dorpat, about the same proportion of senegin which he found in one specimen of the former, amounting to 1·64 per cent. The other main active constituent, polygalic acid, however, though existing in appreciable quantity in the northern senega-root, especially after it has been kept for some time, is only to be found in traces in the Polygala boykinii. In examining the physiological action of senegin, he found that when introduced into the circulation it acted as a violent poison, causing death from asphyxia due to heart paralysis. No effect was produced when senegin was introduced into the stomach—partly, perhaps, because it was to some extent vomited, but mainly because it was not absorbed. In animals which cannot vomit, no toxic effect was observed. Of course the result might have been different if the gastric mucous membrane had been ulcerated or wounded. Again, the subcutaneous administration did not show the same toxic effects as its intravenous injection, but it produced violent local irritation. Dr. Atlass was unable to discover any therapeutic value in senegin.

UTERINE MYOMA TREATED WITH HYDRASTIS.

Dr. Schmidt of Prague has treated with remarkable success a case of long-standing myoma of the uterus, accompanied with copious hæmorrhage, by means of tincture of hydrastis canadensis. Twenty-five drops were given four times a day for three or four months. During this period the hæmorrhage stopped, the menstrual periods became normal, and the tumour decreased very markedly in size.

SAPONIN AND SAPOTOXIN.

Quillaya saponaria was recommended by Professor Kobert as a cheap and efficient substitute for senega, and has since been employed with good results by Goldschmidt, by Maslovski, chief of Professor Kuznets' clinic, and by Dr. Pachorukow of Dorpat. The last-named observer has just published some account of a principle named by Professor Kobert "sapotoxin,"

Digitized by Google

which is contained in quillaya, and also forms part of the preparation sold as saponin, which appears, according to Dr. Pachorukow, to be a mixture of this substance, which is of a toxic character, and of another, lactosin, which is harmless. Sapotoxin has a powerful action on the blood, destroying the red corpuscles and decomposing the oxyhæmoglobin, thus interfering with the absorption of oxygen and causing death by asphyxia.

QUEBRACHO IN SURGICAL PRACTICE.

Dr. Bordeaux of Brussels, who has used quebracho a good deal during the last year or two, speaks very highly of it as a topical application for wounds and burns. The liquid extract is the preparation employed, and it is painted with a brush over the wound like collodion. The slight pain it causes is very transient; it becomes hard in an hour's time, forming a brownish crust, which can only be loosened with the aid of hot water. This crust is quite sufficient protection, no dressing being required. It promotes healing by first intention, and greatly assists the process of granulation.

HYPODERMIC INJECTIONS OF CHLORIDE OF SODIUM IN COLLAPSE.

Dr. Rosenbusch, writing in a Polish journal, describes some cases of collapse from hæmatemesis and hæmoptysis in which hypodermic injections of chloride of sodium acted most satisfactorily.

MEDICAL DEGREES FOR LONDON STUDENTS: PETITION OF THE APOTHECARIES' SOCIETY.

THE following petition, praying to be heard by counsel, in reference to the petition of the Royal College of Physicians of London and the Royal College of Surgeons of England for Charter and to grant degrees, has been forwarded to the Privy Council.

To the Queen's Most Excellent Majesty in Council.

The humble petition of the Master Wardens and Society of the Art and Mystery of Apothecaries of the City of London, humbly sheweth as follows:—

1. A petition has been presented to your Majesty by the Royal College of Physicians of London and the Royal College of Surgeons of England praying for a Charter (hereinafter referred to as the "said Charter") incorporating an equal number of the Fellows or Members of each of the said two Colleges under the name or style of the Senate of Physicians and Surgeons, with power to grant to persons who have obtained qualifications for registration under the Medical Act from either or both of the said Colleges, and shall be otherwise properly qualified, degrees in Medicine and Surgery and with other powers.

2. Your petitioners humbly submit and allege that they, as well as the general public, will be injuriously affected by the granting of the said Charter as prayed, and they object thereto for the following among other reasons.

3. Your petitioners, now known by the name of the Master Wardens and Society of the Art and Mystery of Apothecaries of the City of London, are a corporation incorporated and empowered under letters patent bearing date the 6th day of December, in the 15th year of the reign of King James the First, by the name of "The Master Wardens and Society of the Art and Mystery of Apothecaries of the City of London," and further empowered by an Act of Parliament made and passed in the 55th year of the reign of King George the Third, intituled "An Act for better regulating the Practice of Apothecaries throughout England and Wales," and by an Act of Parliament made and passed in the session of the 37th and 38th years of your Majesty's reign, intituled "The Apothecaries Act Amendment Act, 1874."

4. Under the Medical Act made and passed in the session of the 21st and 22nd years of your Majesty's reign the licentiateship of your petitioners, as well as that of each of the said two Colleges, is a qualification entitling the holder thereof to have his name entered on the Medical Register directed to be kept by the said Act.

5. Under the provisions of the Medical Act made and passed in the session of the 49th and 50th years of your Majesty's reign respecting examinations for the qualifications entitling the holders thereof to have their names placed on the Medical Register the General Medical Council have, upon the application of your petitioners, appointed examiners to assist at the examinations held by your petitioners of candidates for their licentiateship. Your petitioners, with the assistance and under the direction of the assistant examiners appointed by the General Medical Council as aforesaid, hold such qualifying examinations, and no examinations for persons about to become general practitioners are held in higher or more deserved repute.

6. The licentiates of your petitioners number nearly 10,000, nearly the whole of whom practise both Medicine and Surgery. The fees payable in respect of the qualifying examination and diploma of your petitioners are considerably less than those payable in respect of the similar examination and diploma of either of the said Colleges.

7. The qualifying examination of your petitioners is as severe a test of proficiency in Medicine, Surgery, and Midwifery as the examination conducted by the said Colleges, but if the said Colleges are enabled to grant degrees to their members to the exclusion of the licentiates of your petitioners, such prestige would thereby attach to the said Colleges that the diploma of your petitioners would necessarily su[ffer] estimation, and be regarded as of inferior value. If the [ex]penses now attending the acquisition of degrees in [Me]Surgery be removed by empowering the said Colleges to [grant] degrees, the public will expect all medical practitioners to po[ssess] as well as a qualifying diploma, with the result that if the [said] be granted as prayed, not only your petitioners, but the p[ublic] be injuriously affected; many persons who under existing c[ircum]would become candidates for your petitioners' diploma will [prefer] to be candidates instead for a diploma of the said Colleges, [and] as candidates for a degree, and others will be debarred by [the] imposed by the said Colleges from becoming medical practi[tioners].

8. Your petitioners humbly submit that it would be most unjust to their licentiates that they should be debarred fr[om] degrees in Medicine or Surgery which are open to members o[f the] Colleges. The curriculum passed through by the licentiates petitioners in no way differs from that passed through by the of the said Colleges; they attend at the same schools and hos[pitals] comply with the same conditions; and the examination for th[e] of your petitioners is as complete and satisfactory a test of pr[oficiency] as the examination of the said Colleges for a qualification for tion under the Medical Acts. Your petitioners therefore suf[fer] no rights and privileges such as those prayed should be grant[ed] members of the said Colleges which are not at the same time g[iven] the licentiates of your petitioners. Your petitioners submit Charter be granted by your Majesty to the said Colleges, it shou[ld] that all licentiates of your petitioners should be eligible for degr[ees] said Senate upon the same terms and conditions as members o[f the] Colleges, and that the examination held by your petitioners diploma should be an equal qualification for such degrees an[d ex]aminations therefor with the examination of the said Co[lleges] qualifications for registration under the Medical Acts.

9. Your petitioners submit that no new University for the co[nferring] of degrees in Medicine and Surgery is required in London University of London already satisfactorily and fully perform functions of such a university. If the said Charter is granted in prayed, which does not provide of necessity that candidates fo[r] shall be required to pass any examination beyond the examinati[ons] said Colleges for qualifications for registration under the Medi there will be constant danger that the said Colleges, in order t[o] candidates, will require a low standard of proficiency from the c[andi]for their degrees, whereby the value of and prestige attaching t[o] will be diminished and lowered.

10. Your petitioners humbly submit that the said Charter is u[n]sary, that as prayed it would unjustly exclude and prejudice the of your petitioners, deal a most severe blow to the rights and of a body who are universally allowed to be fulfilling their publ[ic] in a most satisfactory manner, as secured by existing Charter a of Parliament, and most injuriously affect the medical profes[sion] the public.

Your petitioners therefore humbly pray that your Majesty will n[ot] to the prayer of the petition of the said two Colleges except upon condition that the said Charter provides that special examinations for shall be compulsory, and that all the licentiates of your petitioner at liberty to present themselves at such examinations, and that the of your petitioners shall be deemed a qualification for candidate examinations as full and complete as any qualification for re[gistration] under the Medical Acts granted by one or both of the said Colle that any licentiate of your petitioners shall be entitled to degree from the said Senate upon the same terms and conditi person who holds a qualification for registration under the Med granted by one or both of the said Colleges. And your petitio pray that, upon the consideration by your Majesty in Council o petition of the said two Colleges, your petitioners may be at attend and be heard by counsel. And your petitioners will ever

*** We are informed that the Society of Apotheca taking active steps, if the petition of the Royal Col the Privy Council should be persevered with in its form, to obtain the assent of the licentiates to the presented by the Society, and also to convene a me the licentiates at their Hall for the like purpose at date in January.

ATTEMPTED EXTORTION FROM A MEDI PRACTITIONER.

A TRIAL of some importance to members of the profession took place on the 17th inst., at the Old before the Common Serjeant. George Wetherall was c with, and found guilty of sending a letter to Mr. A. G of Kilmarsh-road, Hammersmith, demanding £20 o dition that a charge of indecent assault which the de made against Mr. Gittings should not be proceede The facts of the case are briefly these:—

On the 10th of September last defendant's servant Power, a girl of fourteen, called at Mr. Gittings' sur medicine he had prescribed for Wetherall's child Gittings noticed that she looked ill, and learnt fr that she had been ailing for a few days with headac had a pain in the abdomen: her tongue was coated quick, and skin hot. Suspecting typhoid fever, h the girl's consent, palpated the abdomen, and satisfie self that she was suffering from constipation. He pre for her, and told her to see him again in a few

Digitized by Google

but neglected to acquaint her employers of the facts. About three weeks after, Mr. Gittings was summoned at midnight to attend Wetherall for an attack of pleurisy, the girl being sent to fetch him. Mr. Gittings, who had gone to bed, came down and admitted the girl, directing her to wait till he was ready. He attended the defendant for a week, when, on calling at the latter's house, he found that he had gone out with his wife. On being told this by Power, Mr. Gittings stated that he said to her, "Then you are all alone," when she replied, "No, there is a lady upstairs lodging here." This person, Mrs. Mason, was, as will be seen, a material witness for the defence. The same evening Mr. Gittings received a letter from Wetherall, requesting him not to call again until he (the defendant) had consulted his legal adviser concerning something which had come to his knowledge respecting Mr. Gittings' conduct. This letter Mr. Gittings destroyed, and called next day for an explanation. He was then confronted with the charge that he had been guilty of indecently assaulting Laura Power, a charge he indignantly repudiated, as also a proposal made by Wetherall that he should pay him £25 to say no more about it. However, he agreed to meet the defendant upon another occasion, some days later, when Wetherall demanded £20, which was refused, Mr. Gittings, on his part, insisting that the charge should be unconditionally withdrawn. Wetherall then wrote a letter in which this demand was repeated, otherwise he should take proceedings, and the letter began with words to the effect that the writer was unable to accept his (Mr. Gittings') offer—an offer which Mr. Gittings swore had never been made, but which defendant's counsel, Mr. Kisch, interpreted as being an offer of £10. Mr. Gittings then placed the letter in his solicitor's hands, and proceedings were instituted against Wetherall at the Hammersmith police-court, and the case was sent for trial. Mr. Kisch subjected Mr. Gittings to a prolonged and severe cross-examination without succeeding in shaking his evidence in any material point. For the defence, Laura Power deposed that she had been indecently assaulted by Mr. Gittings, not only on Sept. 10th (when she said she was not ill, but admitted on cross-examination to having a pain in her stomach, and to being constipated), but on every occasion that she saw him subsequently, including that day on which she had been sent to fetch him for her master. She also stated that when Mr. Gittings called at Wetherall's house and found him out he kissed her; and Mrs. Mason swore to witnessing this act (which was said to have taken place in the hall) from the landing near her apartments on the second floor. Mrs. Mason further stated that she at once taxed the girl with the familiarity, and obtained from her a confession of the various assaults. This was communicated to Wetherall, who acted as stated. Several witnesses were called to give the defendant a high character. The defence was that Mr. Gittings had been guilty of indecent assault, and that he had offered Wetherall £10 before the letter was written. On behalf of the prosecutor, Mr. Grain pointed to the improbability of the story told by the girl, and the undisputed fact of the threat contained in the letter. In summing up, the judge showed how easily such a charge could be brought against a medical man, and that it would be easy to explain Mrs. Mason's evidence on the ground of imagination, and the girl's confession on her misinterpretation of the examination made by Mr. Gittings on September 10th. It was not until after Wetherall had himself been charged that, at his instance, Power applied for a summons against Mr. Gittings, which the magistrate declined to grant. The jury found the defendant guilty, but recommended him to mercy on account of the weak state of his health and his previous good character. The prosecutor joined in the recommendation of the jury, and the Common Serjeant ordered the defendant to find one surety in £100, and to enter into his own recognisances to come up for judgment when called upon. Whether such a result will act as a deterrent is perhaps open to question, and Mr. Gittings may have erred on the side of mercy in not pressing for the infliction of some punishment; but he knew the man's state of health, and on that ground concurred in the recommendation. At any rate, Mr. Gittings deserves credit for bringing the case into Court, and indeed for resisting what to a professional man must always be a great temptation—the payment of a sum of money to save his reputation from being ruined by a false and baseless charge. We understand that Mr. Gittings incurred heavy legal costs in the action before the case was taken up by the Treasury

MEDICAL TRIAL.

HIGH COURT OF JUSTICE: CHANCERY DIVISION.

(Before Mr. JUSTICE KAY.)

WILLIAMS *versus* HODGE AND CO.

THIS was a motion on behalf of the plaintiff, Dr. John Williams, the well-known obstetric physician, of 11, Queen Anne-street, for an injunction to restrain the defendants, Messrs. Hodge and Co., surgical instrument makers, of Oxford-street, from using, in their trade catalogue, the name of the plaintiff in connexion with a certain instrument of a simple character commonly used in obstetric operations, so as to lead the public to believe that it was the plaintiff's invention. On the use of his name coming to the plaintiff's knowledge, he remonstrated with the defendants, but they refused to expunge his name from their catalogue. The defendants did not appear to the motion.

Mr. RENSHAW, Q.C. (with whom was Mr. Rolls Warrington) read an affidavit by the plaintiff to the effect that it was contrary to the etiquette of the medical profession for a practitioner to advertise himself or to hold himself out to the public as an inventor, and that if he did so he injured himself in the eyes of his fellow-practitioners; and that this attempt to connect the plaintiff's name with an instrument of so simple a character as that in question would tend not only to injure him, but also to render him an object of ridicule in the profession. The plaintiff was supported by an affidavit by Sir William Jenner to the same effect.

Mr. Justice KAY.—This case seems like "Clark *v.* Freeman" (11 Beav., 112), where the Court refused to grant an injunction to prevent a chemist from selling a pill under a false and colourable representation that it was a medicine of the plaintiff, the eminent physician, Sir James Clark. That decision was no doubt a surprise to the profession; but has it ever been overruled?

Mr. RENSHAW.—It has certainly not been accepted as sound. The defendants' untrue representations are calculated to injure the plaintiff in his business, and thus the case falls within "Thorley's Cattle Food Company *v.* Massam" (14 Ch., Div. 763) and that class of cases.

Mr. Justice KAY.—That is a question for the trial. I cannot decide it on an interlocutory application. This is a simple instrument and perfectly harmless; but in "Clark *v.* Freeman" the pill advertised by the defendant was one of a dangerous kind, which the eminent physician who was the plaintiff would never have thought of prescribing.

Mr. RENSHAW.—That case is not considered to be law now.

Mr. Justice KAY.—That is a question for the trial. Supposing the name of some eminent surgeon were attached to a particular instrument, everyone would know that the name was not so used by that surgeon, but by some unscrupulous manfacturer.

Mr. RENSHAW.—I submit that in such a case the wrongful use of the name ought to be restrained. It is, in fact, libellous. In "Hill *v.* Hart Davies" (21 Ch., Div. 798) your lordship granted an injunction to restrain a libel likely to injure a friendly society.

Mr. Justice KAY, in delivering judgment, said that in this case there seemed to have been, according to the evidence, a most unwarrantable use of the name of a gentleman of great eminence in the medical profession by associating it with a particular instrument. That gentleman now asked for an injunction to restrain that use of his name. Had the matter been *res nova*, his lordship should have said that he was certainly entitled to an injunction. A gentleman in the plaintiff's position might reasonably ask, "Why should my name be taken in vain by an unscrupulous manufacturer of surgical instruments?" The defendants had no more right to use the name of this eminent medical man than to take his purse—so his lordship should have said upon his own unassisted judgment if the case had come before him for decision for the first time. But there was the case of "Clark *v.* Freeman," in which the name of Sir James Clark, one of the most eminent physicians of his day, was used by the defendant, a chemist, in connexion with a pill which Sir James had never heard of, and which he would never have dreamt of telling his patients to take. There Lord Langdale refused to grant the injunction asked for. As his lordship had said, that decision was rather a surprising one, and one which he had always thought was not sufficiently considered; but it was a decision from which he did

Digitized by Google

not feel himself at liberty to depart, and from which, upon an interlocutory application such as the present, he had no right to depart. His lordship was not at present aware of any reported case in which "Clark *v.* Freeman" had been considered, or of any case overruling it. Accordingly, the question raised by this motion must stand over until the trial of the action, if the defendants were foolish enough to allow it to be brought on. His lordship thought it right to add that he could not conceive that anyone in the world would suppose this gentleman's professional name would be in the least damaged by this most unscrupulous use of it.—*The Times.*

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN twenty-eight of the largest English towns 5620 births and 3919 deaths were registered during the week ending December 17th. The annual rate of mortality in these towns, which had been 23·5, 22·5, and 21·1 per 1000 in the preceding three weeks, rose again last week to 22·1. During the first eleven weeks of the current quarter the death-rate in these towns averaged 20·8 per 1000, and was 0·7 below the mean rate in the corresponding periods of the ten years 1877-86. The lowest rates in these towns last week were 15·5 in Portsmouth, 16·8 in Brighton, 17·4 in Norwich, and 17·6 in Plymouth. The rates in the other towns ranged upwards to 30·3 in Wolverhampton, 32·9 in Manchester, and 35·7 in Blackburn and in Preston. The deaths referred to the principal zymotic diseases in the twenty-eight towns, which had been 443 and 448 in the preceding two weeks, further rose last week to 500; they included 157 from whooping-cough, 108 from scarlet fever, 80 from measles, 54 from "fever" (principally enteric), 47 from diphtheria, 35 from diarrhœa, and 19 from small-pox. These zymotic diseases caused the lowest death-rates last week in Sunderland and Brighton, and the highest rates in Oldham, Blackburn, and Preston. The greatest mortality from whooping-cough occurred in Manchester, Oldham, Leicester, and Wolverhampton; from scarlet fever in Manchester, Salford, Oldham, Norwich, and Preston; from measles in Nottingham, Bolton, Birmingham, Blackburn, and Derby; and from "fever" in Blackburn, Nottingham, and Preston. The 47 deaths from diphtheria in the twenty-eight towns included 23 in London, 5 in Liverpool, 3 in Oldham, 3 in Newcastle-upon-Tyne, 2 in Bristol, 2 in Preston, and 2 in Huddersfield. Small-pox caused 17 deaths in Sheffield, 1 in Bristol, and 1 in Preston, but not one in London or in any of the twenty-four other large provincial towns. The metropolitan hospitals receiving cases of small-pox contained 10 patients on Saturday last, corresponding with the number on the previous Saturday. The number of scarlet fever cases in the Metropolitan Asylum Board hospitals and in the London Fever Hospital at the end of the week was 2498, against 2726 and 2667 on the previous two Saturdays; the cases admitted also showed a further considerable decline from the numbers in recent weeks. The deaths referred to diseases of the respiratory organs in London, which had been 560, 455, and 408 in the preceding three weeks, were last week 413 and 129 below the corrected average. The causes of 101, or 2·5 per cent., of the 3919 deaths in the twenty-eight towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Portsmouth, Brighton, Preston, and in three other smaller towns. The largest proportions of uncertified deaths were recorded in Hull, Sheffield, and Halifax.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 25·0 and 22·7 per 1000 in the preceding two weeks, was 23·0 in the week ending Dec. 17th; this rate exceeded by 0·9 the mean rate during the same week in the twenty-eight large English towns. The rates in the Scotch towns last week ranged from 16·4 and 16·5 in Greenock and Leith, to 24·9 in Glasgow, 27·0 in Dundee, and 35·0 in Paisley. The 574 deaths in the eight towns showed an increase of 7 upon the number in the previous week, and included 26 which were referred to whooping-cough, 15 to measles, 9 to scarlet fever, 9 to "fever" (typhus, enteric, or simple), 9 to diarrhœa, 7 to diphtheria, and not one to small-pox; in all, 75 deaths resulted from these principal zymotic diseases, against 77 and 79 in the preceding two weeks. These 75 deaths were equal to an annual rate of 3·0 per 1000, and exceeded by 0·2 the mean rate in the week from the same diseases in the twenty-eight English towns. The fatal cases of whooping-cough, which had been 28 and 29 in the preceding two weeks, declined last week to 26, of which 14 occurred in Glasgow, 4 in Aberdeen, 3 in Edinburgh, and 3 in Paisley. The deaths from measles, which had increased in the preceding four weeks from 8 to 14, further rose last week to 15, and included 5 in Edinburgh, 5 in Dundee, and 3 in Leith. The 9 fatal cases of scarlet fever showed a decline of 5 from the number in the previous week, 4 being returned in Glasgow, 2 in Edinburgh, and 2 in Dundee. The 9 deaths referred to "fever," on the other hand, showed an increase upon the low numbers in recent weeks, and included 3 in Glasgow, 3 in Paisley, and 2 in Edinburgh. The 9 deaths attributed to diarrhœa were below the average for the season; while the 7 fatal cases of diphtheria exceeded the numbers in recent weeks, and included 3 in Glasgow, 2 in Edinburgh, and 2 in Greenock. The deaths referred to acute diseases of the respiratory organs in the eight towns, which had been 165 and 143 in the preceding two weeks, rose again last week to 163, but were 11 below the number returned in the corresponding week of last year. The causes of 65, or more than 11 per cent., of the deaths registered in the eight towns during the week were not certified.

HEALTH OF DUBLIN.

The rate of mortality in Dublin, which had increased in the preceding four weeks from 33·8 to 35·6 per 1000, further rose to 38·7 in the week ending December 17th. During the first eleven weeks of the current quarter the death-rate in the city averaged 31·7 per 1000, the mean rate during the same period being but 19·8 in London and 19·7 in Edinburgh. The 262 deaths in Dublin last week showed a further increase of 21 upon the numbers in recent weeks; they included 12 which resulted from scarlet fever, 5 from measles, 3 from whooping-cough, 2 from "fever" (typhus, enteric, or simple), 2 from diarrhœa, and not one either from small-pox or from diphtheria. Thus the deaths resulting from the principal zymotic diseases, which had been 31 in each of the previous two weeks, declined last week to 24; they were equal to an annual rate of 3·5 per 1000, the rate from the same diseases being 2·7 in London and 2·8 in Edinburgh. The fatal cases of scarlet fever, which had been 13 and 15 in the previous two weeks, declined last week to 12. The deaths last week from each of the other zymotic diseases also showed a decline from the numbers in the previous week. The deaths of infants corresponded with the number in the previous week, while those of elderly persons rose to 83 from 51 in the previous week. Three inquest cases and 3 deaths from violence were registered within the city; and 80, or nearly a third, of the deaths occurred in public institutions. The causes of 37, or 14 per cent., of the deaths in the week were not certified.

THE SERVICES.

WAR OFFICE.—Army Medical Staff: Brigade Surgeon Henry Carden Herbert, M.D., F.R.C.S.I., is granted retired pay, with the honorary rank of Deputy Surgeon-General, ranking as Colonel (dated Dec. 21st, 1887).

ADMIRALTY.—In accordance with the provisions of Her Majesty's Order in Council of April 1st, 1881, Fleet Surgeon Edward Jones Butler, B.A., M.D., has been placed on the retired list of his rank (dated Dec. 7th, 1887).

ARTILLERY VOLUNTEERS.—1st Fifeshire: Robert Balfour Graham, Gent., to be Acting Surgeon (dated Dec. 17th, 1887).

RIFLE VOLUNTEERS.—2nd Volunteer Battalion, the Worcestershire Regiment: Surgeon T. E. Underhill, from the 1st Volunteer Battalion, the South Staffordshire Regiment, to be Surgeon (dated Dec. 17th, 1887).—1st Dumbartonshire: Acting Surgeon A. Hay, M.D., resigns his appointment; also is permitted to retain his rank, and to continue to wear the uniform of the corps on his retirement (dated Dec. 21st, 1887).—2nd Volunteer Battalion, the Queen's Own (Royal West Kent Regiment): Ernest William White, M.B., to be Acting Surgeon (dated Dec. 21st, 1887).—18th Lancashire (Liverpool Irish): Acting Surgeon G. A. Raverty resigns his appointment.

(dated Dec. 21st, 1887).—14th Middlesex (Inns of Court): Acting Surgeon T. W. C. Jones to be Surgeon (dated Dec. 21st, 1887).—1st Volunteer Battalion, the Prince Albert's (Somersetshire Light Infantry):—John Maurice Harper, Gent., to be Acting Surgeon (dated Dec. 21st, 1887).—1st Volunteer Battalion, the South Staffordshire Regiment: Surgeon H. H. Smith, from the 1st Volunteer Battalion, the Worcestershire Regiment, to be Surgeon (dated Dec. 21st, 1887).

Correspondence.

"Audi alteram partem."

SCARLET FEVER, SMALL-POX, AND COW-POX.

To the Editors of THE LANCET.

SIRS,—In your issue of Dec. 17th you give an abstract of Dr. Klein's paper, read at the Epidemiological Society, on "Some of the Infectious Diseases common to Man and the Lower Animals," and also an abstract of Professor Crookshank's investigation into the so-called Hendon cow-disease and its relation to scarlet fever in man. With your permission, I would like to make a few remarks on some of the points referred to in these papers, as they are of some importance.

The first is with regard to the relation of human variola and cow-pox. The popular notion in this country is that cow-pox is merely small-pox modified by its passage through the cow, and Dr. Klein brings forward this notion in support of his contention that the mysterious cow disease at Hendon was scarlatina, or, at any rate, produced that malady in people who partook of the milk of the affected cattle. Now, I have for years, in your columns and elsewhere, maintained that human variola and vaccinia are not the same disease, but are quite distinct, and cannot by any known means be transformed. I still maintain this, in the face of the assertions that Ceely, Badcock, and one or two others, have succeeded in converting small-pox into cow-pox; and if Dr. Klein relies upon these to establish his position with regard to an eruptive mammary disease of cows giving rise to scarlet fever in mankind, then I am afraid he stands upon very shaky ground. As Dr. Klein himself acknowledges, he utterly failed to effect the transformation of small-pox into cow-pox, even when acting under the direction of Mr. Ceely, and experimenting under the most favourable conditions on more than thirty milch cows and heifers. And I will make bold to say that if Dr. Klein carries on experiments all his life in this direction he will be unsuccessful, as have several continental commissions (not alone the French commission under Chauveau), and every individual—myself among the number,—except the three or four above mentioned. Clinically and anatomically they differ widely, and their points of similarity are few and trivial. All attempts to convert variola into vaccinia by inoculating cows with small-pox matter have failed—have failed in the hands of careful and most able experimentalists, and they will fail. But in this case we can resort to our heart's content to experiments upon our own species to prove whether the two maladies are due to one virus—a course which we can so seldom adopt with regard to other diseases. We can inoculate human beings with vaccine virus with the view of transforming vaccinia into variola, and if the latter is the former the results in every case should not be doubtful. Transferred to its original soil, the virus should be itself again, and produce small-pox with all its well-marked features. Since the days of Jenner countless millions of persons have been subjected to this experiment, if we may so designate every-day vaccination; and I ask if there is an instance on record in which vaccinia became variola? I certainly know of none. Surely it is as reasonable—if not more so—to attempt to convert vaccinia into variola as to transform the latter into cow-pox. Compare the ease with which vaccinia can be transmitted from calf to calf, from the latter to the child, and *vice versâ*, throughout endless generations, and without the slightest tendency to become variola, with the very few recorded cases of supposed production, experimentally, of the disease from small-pox virus, which was for ever changed by implantation in the body of the cow.

The virus of cow-pox and that of small-pox differs in no respect from the viruses of other contagious diseases in regard to preserving its specific potency. The viruses of anthrax, tuberculosis, glanders, rabies, scarlatina, measles, &c., will always produce none other but these diseases, and if the symptoms produced by them when inoculated in other species of creatures than those to which they are native are somewhat different, yet when carried back to their original soil they are again the same in everything. I am quite astonished at the way medical men in this country have treated this question of identity of cow-pox and small-pox, and accepted the assertion as to this identity without resorting to proof.

With regard to the existence of scarlatina in cows, or a disease in them which will give rise to that malady in people through ingestion of milk, I am seriously inclined to doubt it. The disorders of cows have been closely studied of late years by veterinary surgeons, and nothing resembling scarlet fever has been observed. Scarlet fever in man, if derived from the cow, would also be that disorder in the bovine. I should not like to be considered dogmatic in the matter, but I think it will eventually be found that a mistake has been made as to this Hendon disease, and that Professor Crookshank is on the right track. We shall then have to express regret that such a panic should have been caused and such serious injury should have been done to a most important industry through over-anxiety and haste to protect the public from a dreaded scourge.

With regard to Professor Crookshank's statement that veterinary surgeons he inquired of informed him that the disease he saw affecting the cows' udders was very well known to them, but was not described in text-books of veterinary medicine, I may mention that in my work on "Veterinary Sanitary Science and Police," published twelve years ago, in the section on Variolous Disease in Animals, I particularly described cow-pox and the diseases of the udder with which it might be confounded. Cow-pox and horse-pox are not at all rare diseases.

I am, Sirs, yours truly,

GEORGE FLEMING,

Dec. 21st, 1887. Principal Veterinary Surgeon of the Army.

THE TREATMENT OF CANCER.

To the Editors of THE LANCET.

SIRS,—Mr. Jennings, in your number of the 17th, asks me to give him an answer to several questions: In what sense do I use the term "cure," and whether I believe Dr. Smith's case[1] was one of cure, with non-recurrence for nineteen years? I answer: I would accept a case of cancer as having been cured that fulfilled the following conditions: that after the removal of the cancer, by whatever mode of treatment adopted—remedies, external or internal,—there being also evidence of complete restoration to health, the patient remained without any reappearance of the disease throughout the remainder of life—throughout a life in which death ultimately took place from causes common to the break-down, from ordinary wear and tear, of natural structures. I cannot therefore accept Dr. A. F. Smith's case as a "cure," deeply valuable as it may be as an instance of prolonged immunity from recurrence, and confirming, in selected cases, the extreme value of the knife. In what sense do I speak of cancer "infiltrating textures around its origin"? Well, I always speak of a cancer as almost always infiltrating the part or tissue it attacks, the natural character of the structures being either absorbed or otherwise destroyed and replaced by new material. The clinical recognition of adjacent glandular contamination is surely so obvious that I may be pardoned for not offering on the present occasion any description of its features.

I am, Sirs, yours faithfully,

Birmingham, Dec. 20th, 1887. OLIVER PEMBERTON.

To the Editors of THE LANCET.

SIRS,—Like many others, I have tried Chian turpentine, and, though not regarding it as a specific, have still been very much impressed by its effects in two or three cases of undoubted cancer. An old lady, the subject of cancer of the cervix, took the turpentine for one or two months.

[1] THE LANCET, 1887, vol. ii., p. 565.

Digitized by Google

The changes observed were these: The pain, which was at first excessive, was decidedly relieved; the discharge changed from a thin, grumous ichor, to a more or less profuse glairy blood-speckled discharge; but, to me, the most remarkable change seemed in the melting down, to a great extent, of the encephaloid swelling, first seen in and around the os uteri. That the disease was cancer I have no doubt, this also being the opinion of my friend Dr. Marriott of Leicester, to whom I had sent the case for consultation. The patient died, however, worn out at last by pain and general exhaustion, for, like many other cancer patients, she yielded to despair and gave up all treatment. From a vaso-motor point of view, the wonder would be if Chian turpentine had not some notable effect in cancer in any of the pelvic organs. We know that the turpentines have, or seem to have, an elective affinity for the abdominal and pelvic arterioles, and in small continued doses constrict these vessels, even to infarction of mucous tissue. It might be asked, If this is so, how comes it that the diseased portions are those only acted on? But when we consider that the arterioles supplying a cancroid mass must be constantly in a state of spasm (hence the pain) from the cancer poison, we need not wonder that a little more constriction, the result of the continued doses of Chian turpentine, will bring about that wasting and death of the cancerous mass so much desired by those treating this terrible malady. Chian turpentine, like all other turpentines, appears to have a decidedly constringing effect on the arterioles and capillary vessels of the pelvic mucous membranes, and acts in the presence of cancer—unfavourable cases of cancer—much as ergot does in some fibroid diseases of the uterus.

I am, Sirs, yours truly,

Rothwell, Northampton, Dec. 19th, 1887. JAMES MORE, M.D.

To the Editors of THE LANCET.

SIRS,—In THE LANCET of the 19th ult. Professor Clay has recorded some additional cases of the successful treatment of cancer by Chian turpentine, and in a leading article contained in your issue of the 3rd inst. you have made some comments upon this subject. The following brief record of a case of well-marked epithelioma of the tongue, in which this treatment was adopted, may, especially as the subject is again brought under discussion, be considered worth publishing. Although the patient succumbed suddenly to causes other than the disease itself, the marked influence of the treatment in checking its onward progress, in improving its appearance, and in ameliorating its symptoms, was distinctly in favour of the medicine.

Mrs. S——, aged about sixty, consulted me on Dec. 31st, 1886, suffering from a painful indurated tumour on the side of the tongue, extending from near the root to within about two inches of the tip, and occupying nearly half of the transverse diameter, with jagged, sloughing ulceration running along the centre, having hard, raised, and everted edges. I could not trace it to any local source of irritation, unless a loose, rather sharp molar tooth might have so acted. It must have grown rapidly, as I had seen her the previous September, and she had then no symptom of the malady. Its extent, especially towards the pharynx, I considered precluded the idea of operation. Encouraged by the reports of success in some cases of treatment by Chian turpentine, I determined upon giving this a fair trial. I obtained the medicine, through Mr. Grose of this town, from Messrs. Southall. The disease had produced an evident effect on her general health and appearance. She suffered acute pain, which deprived her of rest; swallowing was very difficult, often impracticable, much of the food being rejected, partly through the nose, some before, some after, reaching the stomach; speech, of course, imperfect. After some other treatment, which I need not detail, the Chian turpentine was first given on Jan. 5th, 1887. After about a fortnight, I found there had been a want of regularity in its administration, although retained by the stomach better than most other things. After this it was persevered with regularly for about six weeks before there was any perceptible improvement, and I began to anticipate failure. Soon after this, however, there was some mitigation of pain, so that the morphia draughts she had been taking at night were less required and then discontinued; the diseased mass, which had been progressively increasing, appeared to be less active, and after a further period the surface presented a less malignant aspect, the ulcer appearing less deep and its edges less raised and everted. The improvement continued to be so marked, both as to the appearance of the local disease, the diminution of pain, and the power of swallowing and of speech (which had become nearly unintelligible), that I asked my friend Dr. Rawlings to see the case, so that I might have his evidence should it end in recovery. In the night of March 23rd the patient had an attack of syncope, from which she partially rallied, but relapsed, and died at an early hour in the morning. I then found that the nourishment which was ordered had, from causes which I need not here enter into, not been regularly given, and the patient sank, I believe, from exhaustion, no doubt partly induced by the disease, but chiefly from insufficient nourishment. My impression is that the disease would have subsided if strength had been sustained. The local applications used by Professor Clay were soon discontinued—the chromic acid on account of the pain induced. Unless, therefore, the check to the onward and otherwise, I believe, inevitable progress of the malady, and the obvious amendment which followed, were due to the influence of the medicine, I do not know to what to attribute them.

The question may be asked, Is it or is it not a fact that cases of marked and, as far as our present diagnostic powers can determine it, unmistakable cancer, especially epithelioma, have yielded to this treatment—such cases as, according to all experience, would, unless surgically removed, have otherwise gone on from bad to worse? The evidence we have compels us to answer this question in the affirmative. Failures cannot destroy the force and value of such experience. In none of the cases recently referred to is it stated how long the treatment was continued before it was given up as a failure.—I am, Sirs, yours truly,

Swansea, Dec. 10th, 1887. GEORGE PADLEY.

THE NOMENCLATURE OF PHYSICAL SIGNS.

To the Editors of THE LANCET.

SIRS,—In a recent discussion in your columns on the nature of a cardiac murmur, a side issue was raised in respect of the name best adapted to describe the bruit. On this point there was difference of opinion even among those who were agreed as to mode of origin, and the names auricular systolic, presystolic, and late diastolic were severally advanced as each best adapted to name one and the same phenomenon. For the choice of any one of these three names a reasonable cause may be shown, and it is a matter of very little moment whether, by common consent, preference should be given to one of these three names, or all three should persist in use—of little moment because each name is unambiguous, is readily understood. Far otherwise is it in respect of the nomenclature of physical signs in general; here serious confusion exists, and each returning year the teacher is confronted by a very difficult problem—to wit, what terms, from a very large vocabulary, he shall select as least likely to give rise to misunderstanding in the future. The problem is becoming an increasingly difficult one, for schools are multiplying, and text-books are multiplying, and Babel is imminent. The terminology current at one hospital is not that current at another, and in the attempt to reconcile the one with the other all finer distinctions are lost. It cannot be maintained that the question is not a vital one, or that with a little patience one can, as a rule, make out the drift of the description; such contention could have but one meaning—viz., that accurate definition was superfluous and delicacy of perception unessential; it would come also with very bad grace from a department of knowledge which claims to be both a science and an art. That I should take up this question in detail will not be necessary. All of us know of the present confusion; many have felt its inconvenience keenly. How much time is spent year after year by students in mastering or endeavouring to master the terminologies of their own particular schools! How great is the disappointment when it is discovered that the currency of each is a very limited one! To add to the misfortune, it is the earnest students who suffer, not the men who are content with "râles, don't ye know," for every sound, from a tracheal rattle down to—well, the finest sounds *they* are capable of recognising. Admitting, then, the need for reform, how may it be effected? Utopian as it may at first sound, I can only suggest that it should be settled in conference. The proposal sounds formidable, but I cannot think that it really is so formidable as it sounds, or

Digitized by Google

that it is Utopian to hold that people should ever come to agree on questions of this kind; were it, however, both the one and the other, the need appears to me so pressing that I should still feel compelled to urge the only method which can be successful. The first step towards any such conclusion would be that each school should agree upon its own teaching; the next that this teaching should be represented at a council of delegates. I believe that the proverb, "Il n'y a que le premier pas qui coûte," would prove true here; and this first step—surely it ought to be taken by each teaching body. That when all should be said and done there would remain moot points, one must of course expect; but of the multitude of terms chosen on no definite principle which we now possess, we might with advantage lose many—redundancy is a great defect of our present system. What do we want with bronchial breathing, tubular breathing, blowing breathing, tracheal breathing, &c.? And the râles—who shall name them? It is not for me to suggest a system, though I would venture to say just this much—that any nomenclature should, at all events in the first instance, be in outline rather than in detail. It is a true principle in art—be pure in your outline; the filling in is of secondary importance. Then the nomenclature should be, as far as possible, on one principle only; and, as far as possible, this principle should be descriptive, all terms implying a theory being avoided. Where possible, also, descriptive terms should be such that ready reference may be made to the analogue: e.g., a percussion sound is described as *osteal;* if asked what is meant, it will always be possible to reproduce the sound to the questioner. We should, lastly, endeavour to conform our terminology to the terminology in use in the physical sciences—always, however, to the exclusion of theory.

I do not, of course, suggest that a new language should be coined; indeed, I cannot help hoping that we should not have far to go to find a system ready to our hands which, with a modification here and there, would answer every purpose—I refer to Dr. Gee's book on "Auscultation and Percussion," for which I trust I may express the great admiration I feel.

I am, Sirs, your obedient servant,

Welbeck-street, Dec. 10th, 1887. HARRINGTON SAINSBURY.

HYDROPHOBIC VIRUS DESTROYER.

To the Editors of THE LANCET.

SIRS,—In view of the numbers of deaths there have been lately from hydrophobia, I have designed a "virus destroyer" as a preventive, which, if adopted, would go a long way towards preventing that fearful disease. It is in the form of a small case containing a very soluble prepared point composed of compressed nitrate of potash (10 parts), and corrosive sublimate (2 parts), and meant for public and police use, and to be attached to the ordinary key ring, and thus be always at hand for instant use in cases of dog-bite or poisoned wound. The composition of the virus destroyer is not the chief point. I only chose corrosive sublimate because it is the strongest at present known, and will keep without risk or loss. The main thing is to have an antidote at hand for instant use. These could be made cheaply, and be in the hands of everyone, and for the poor the police could carry them and be instructed in their use. At present it is the delay that is so fatal before aid can be got in many outskirts &c., where dogs are and no help is near. Their use is not meant to supersede medical advice, which could be sought as hitherto, but the sufferer would then be treated with the virus probably destroyed, and not, as now, after it has been absorbed. A dog-bite is usually a superficial scratch or tear, and not a sharp puncture, and even if the canine teeth be inserted deeply the saliva gets mainly or entirely rubbed off and left on the surface. The lunar caustic still used is decomposed into chloride and so rendered inert. Setting aside extreme cases (which I believe are attended with least risk on account of copious bleeding), in by far the majority of cases the virus destroyer would destroy the virus. Full directions would be given with each, and instructions that after use a doctor should be at once sought. The moral effect, too, of the use of these would be great; many of the deaths arise from fear, and I have no doubt that in these fatal cases, when even the parts bitten were excised, either it was done too late or the bad result was due to mental impression.

I may add that from the first, and all through your various reports, I have never been able to see anything but risk in Pasteur's treatment. Experiments on animals and bites on a nervous man who has heard of the ravages of rabies are widely different. It by no means follows that, for reasons stated before, all persons bitten by rabid dogs will take hydrophobia or that persons bitten by healthy dogs will not take it. Personally, were I bitten, and even when amongst dogs, my mind would be immensely relieved by knowing that always in my pocket there lay a probably immediate antidote.

As regards the strength of corrosive, R. Koch of Berlin found that the spores of anthrax, perhaps the hardiest of known forms of germ life, could be destroyed by such weak solutions as 1 in 10,000 and 1 in 20,000.[1] Risk of poisoning would be *nil.*

I am, Sirs, your obedient servant,

Morecambe, Dec. 4th, 1887. THOS. MACCALL, M.D.

*** The notion advanced by Dr. Maccall is decidedly worth entertaining; his method presents nothing which can be objected to on *a priori* grounds, and may prove of great value. There is nothing so convincing, however, as experiment. The antiseptic pencils would also be useful in rendering ordinary small wounds aseptic.—ED. L.

ALBUMINURIA IN THE APPARENTLY HEALTHY.

To the Editors of THE LANCET.

SIRS,—With reference to the letter from Dr. Ralfe in your issue of last week in connexion with my contribution to THE LANCET of Dec. 10th, I shall be obliged if you will kindly permit me to say a few words. When writing the paper, of some parts of which the contribution just referred to was a summary, I made a careful study of Dr. Ralfe's most valuable book on renal diseases, and was much rewarded thereby; but I think I am to be excused if, on reading his article in THE LANCET of Oct. 23rd, 1886, written some time after the publication of the book, I came to the erroneous conclusion that Dr. Ralfe had in the meantime found reason to modify his opinion on the subject. For these are his words: "Writers, under the terms 'intermittent albuminuria,' 'albuminuria of digestion,' 'cyclical albuminuria,' the 'albuminuria of adolescents,' &c., have described a condition in which, without any great disturbance of bodily health, and apart from any definite renal disease, albumen is found more or less continuously in the urine. Although the question, whether these forms of albuminuria, as the various terms applied would imply, are really in each instance distinct, or whether they are brought about by the same pathological factors, may still be considered by many an open one, yet I think there are many considerations which would make us decide entirely in favour of the latter supposition. In the first place, taking "any one of the above forms of albuminuria, we find that though it may occur in any sex and at any age, yet the largest proportion of recorded cases will always be among young adult males. Again, these forms of 'albuminuria' are nearly always found occurring among individuals who are either suffering from some constitutional taint, inherited or acquired—such as gout, rheumatism, syphilis, or malaria, —or in whom some disturbance of the vaso-motor system can be demonstrated. ..... The urine, too, in all cases of functional albuminuria exhibiting these features, so far as they have come under my observation, presents two characteristic features — viz., increase of urea and an abnormal amount of urinary pigment; whilst, but as a less constant phenomenon, bile pigment can also usually be detected. ..... There is always a degree of anæmia ..... sufficient to be determined by the hæmocytometer." In my original paper I had come to compare my own results with those of others, and I find there the following reference to Dr. Ralfe's: "It is the exception in my experience to find any constitutional taint, and the *demonstration* of a vaso-motor disturbance is certainly impossible in many cases, except by the presence of the albuminuria itself, though a decided want of tone in some instances is to be found. In one group of cases an increase of urea and pigment is visible, but certainly not in the larger

[1] Vide reports of the German Imperial Board of Health; also Listen on Sero-sublimate Dressings, THE LANCET, 1884.

Digitized by Google

number, and anæmia cannot be said to be present in a considerable proportion.

Expressing my indebtedness to Dr. Ralfe for much valuable information afforded by his work on Renal Diseases, and to you for the valuable space which you have given me,

I am, Sirs, yours faithfully,

Grays, Essex, Dec. 20th, 1887. ALEX. W. STIRLING.

DEGREES FOR LONDON MEDICAL STUDENTS.

To the Editors of THE LANCET.

SIRS,—I notice in this morning's *Daily Leader* that a Convocation will be held in Bishop Cosins' library (wherever that may be), Durham, for the purpose of submitting a petition to the Queen against the proposal to bestow upon the Royal College of Physicians, London, and the Royal College of Surgeons, England, the power to confer degrees in Surgery and Medicine. As there are no reasons given in support of the petition, I have been trying in vain to find a single one, but without success. I have, however, thought of three possibilities: (1) It may be thought that the examiners giving the degrees in London at the Royal Colleges of Physicians and Surgeons (always till now looked up to as the greatest teachers in the land) are not fit, when compared with the University of Durham teachers, to confer degrees. (2) It may be that the facilities for teaching and hospital work in London are inferior to those of the University of Durham, and that the teaching of the other provincial schools is as bad as London itself. Or (3) it may be that, if degrees are given at the College of Physicians and Surgeons, London, they will be preferred to the Durham one; or is it, again, that the house at London and Durham, divided against itself, cannot stand, or, in other words, "save me from my friends"?

We have yet to learn that the noblest examples of our profession have come from the older Universities; in fact, almost without exception they have been educated in the place, or at any rate have obtained their qualification in the place, which the petition of the University of Durham would like to stop from granting degrees.

Again, where is this great superiority of the University of Durham, and in what does it differ from other provincial medical schools? Why should not—measuring things on the same level—all provincial schools be universities? To this question I can give no answer.

I think that we often see gentlemen signing petitions far behind the times—gentlemen 500 years behind the times,—and it makes one almost believe that, had they the power, they would bring back the old-fashioned medicine of charming, anointing, embalming, and witchcraft, for they evidently think that a degree of a University cannot be improved by the greatest teachers or the largest field of material, or else they would not oppose the granting of degrees by the London Colleges of Physicians and Surgeons.

It is to be hoped that the time will come when, for the advancement of our noble calling, ability and facilities for knowledge, when found, will be assisted and pushed on rather than stopped by a narrow-minded University.

I am, Sirs, yours truly,

Newcastle-on-Tyne, Dec. 18th, 1887. JOHN WHITEHOUSE.

THE HEALTH OF NEWCASTLE-UPON-TYNE.

To the Editors of THE LANCET.

SIRS,—In last week's Northern Counties Notes your "own correspondent" recalls the familiar quotation, "Incidit in Scyllam qui vult vitare Charybdim." Whilst demurring to the circumstance of the School Board regulations having been blamed as a factor of the recently increased mortality (in which I concur with him, for in the way of cause and effect there is, to my mind, no connexion between the two), he proceeds to arraign what he terms the "bureaucratic management of the city," and affirms that "disease is often concealed for fear of notification and inspection, with removal of patients and beds." If your correspondent can give me the names and addresses of any such cases I hope he will do so. His allegation involves either a charge of concealment by a medical practitioner, or one of wilful [illegible] on the part of the householder to call in a doctor, [illegible] to wilful concealment. The former, I can [illegible] to the notes he has made [illegible] case, and occupying [illegible]

to have given the sanitary authority intima[tion] circumstances at the time of their occurrence.

How, as your correspondent seems to conject[ure] new sanitary arrangements," as he calls notificati[on] spection, have made the people neglect cleanliness[,] the reach of my imagination. I utterly fail also[,] him in his closing flight of fancy in which he att[ributes] high death-rate to a fantastic combination of h[ard] ment, poverty, and streams of infants nightly r[un] wash down raw tripe at "long bars." Such a state[ment] in Newcastle is certainly not within the range of [my] rience. I am, Sirs, yours obediently,

HENRY E. ARMSTRONG,

Dec. 21st, 1887. Medical Officer of

THE EYE INFIRMARY, NEWCASTLE-ON-T[yne]

To the Editors of THE LANCET.

SIRS,—Knowing how ready you always are to [help] anything which is of professional interest and utility[,] feel obliged if you will publish the following statem[ent]

Owing to the pressing nature of the needs of the [Eye] the committee of the above-named institution in t[he] 1885 found it necessary to purchase a site and build[a] hospital for the treatment of ophthalmic diseases. [Thanks] to the generosity of the public, who came liberally [to the] aid, they have successfully accomplished this [great] object, and the northern counties are now in posses[sion of a] model hospital, which is in full work. It has been s[aid] that one thing would add to the completeness [of the] establishment, and that is the foundation of a r[eference] library of works bearing on ophthalmic practice. [Many] medical men having old books, authors and others[,] surplus copies of their works, would, I feel sure, [be glad] when our wants are made known. We shall be h[appy to] pay the carriage of any parcel of books or periodi[cals] dressed to me at the hospital, and their receipt wi[ll] mally and thankfully acknowledged.

I am, Sirs, yours faithfully,

CHRISTOPHER S. JEAFFRESON, F.R.[C.S.]

Dec. 1887. Senior Surgeon to the Hospital.

THE RECENT TRIAL FOR MURDER AT [Newcastle]

(From our Special Correspondent.)

FOR the past week the trial of Surgeon-Major [Cl]ark of the 53rd Regiment, for the murder of his wife [Ma]ry has engrossed the attention of the inhabitants of [Newcastle] to the exclusion of every other topic of conv[ersation]. Home Rule, Plan of Campaign, Land League, [and] into insignificance in face of this one all-absorb[ing] nothing else was talked of save the probabilit[ies] verdict which the jury would bring in, whether [of] or a disagreement, the most sanguine not anticip[ating] of acquittal. That such interest should be [taken] case need not surprise us when we reflect upon [the] status of the parties concerned: Surgeon-Major [Clark] addition to his half-pay, being possessed of [some] private means; whilst his late wife was the [daughter] highly esteemed family resident in Essex. They [had] married eighteen years, and had a family of [four]. The case was tried before a special jury in the [Queen's] Mr. Justice Murphy, whose long experience as [a] lawyer eminently qualified him for the [task]. [We] forwarded you the evidence as it was [produced] day to day; it now only remains for me to [make] general comments on the case. And first of all, [I] to make some remarks on the demeanour of [Clark] who entered the dock evidently confident of [his] an appearance which he preserved on the [first] the trial. On the third day, however, he [was] nervous and anxious, an appearance which [was] on the fourth day, the last day of the trial, [when] the jury brought in the dread verdict [of] seemed to be the only unconcerned [person]. When asked why sentence of death [should] upon him, he proceeded in a [clear] consistent upon the evidence [adduced] to the notes he had made [during] case, and occupying some forty [minutes]

Digitized by Google

The case for the Crown, as laid before the jury by the Attorney-General, was that on some three or four occasions he had administered small doses of arsenic, and that on the last occasion he gave a larger dose, supplementing its action shortly before death by strychnine. The administration of strychnine was evidently surmised from the fact that some cries were heard from deceased very shortly before her death, and this although no tetanic rigidity was at any period manifested in the corpse. The *repeated* administration of arsenic was inferred from the symptoms present during the last three weeks of her life—vomiting and purging, with periods of intermission—also on the evidence of one lady that her eyes were affected for two days, but the last few days of her life she did not observe them to be affected. No satisfactory evidence was adduced of the existence during this period of the characteristic burning pain produced by large doses of arsenic, nor yet of the presence of cramps at any period of her illness. The case for the Crown was supported by the analysis conducted by Professor Pearson, of the Queen's College, Cork, who gave his evidence in a manner that I have rarely seen equalled in a court of justice. Calm, cool, gentleman-like, he described the various tests he employed to detect the presence of arsenic, finally producing three tubes containing arsenic, each sample being the result of a different mode of analysis. There was but one blot in Professor Pearson's evidence. On August 1st, at the magisterial inquiry, he swore that, as the result of his quantitative analysis, "the liver contained over three grains." On September 5th his previous deposition was read over to him, which, with some slight corrections, he reaffirmed, leaving this statement standing; but a very few days before the trial he amended his depositions, reducing the three grains to 1·28 grains so found—a fact eagerly laid hold of by the prisoner's counsel, and upon which they principally grounded the defence. Professor Pearson's explanation of this discrepancy was that, upon the occasions when he made his depositions, he had not his notes by him—that they were at the College. Be this as it may, however, he produced before the jury in his tubes quite enough arsenic extracted from the body of the deceased to account for her death. Dr. Cross having registered his wife's death as being the result of typhoid fever, Professor Pearson swore, relying on the absence of intestinal lesions, that she did not die of typhoid fever. It is, however, a question open to interesting discussion as to the appearance which the intestines of a person who died in the earlier stages of typhoid, previously to the setting in of ulceration, would present some fifty-six days after interment. Dr. Cross was proved repeatedly to have stated that his wife had heart disease; Professor Pearson swore that the organ was sound so far as post-mortem appearances went: statements perfectly reconcilable, as every practising physician knows; and it is only fair to Dr. Cross to observe that his statement was corroborated by the evidence of several of the witnesses produced by the Crown.

The leading counsel for the prisoner, Mr. Atkinson, Q.C., opened the defence in a speech which was beautifully delivered, felicitously phrased, and closely argued, basing his defence principally on the improbability of one conscious of guilt committing the mad acts that the prisoner had done—acts certain to excite suspicion and to induce inquiry. He arraigned the skill of the analyst, dwelling at length on the blot in his evidence already alluded to, concluding his speech with a magnificent peroration which wrested from an evidently hostile audience applause, which, however, was promptly and severely silenced by his lordship, who delivered his charge to the jury in such terms as to leave but little doubt in their minds of the prisoner's guilt.

LIVERPOOL.

(From our own Correspondent.)

LORD WOLSELEY ON ATHLETICS.

ADVANTAGE was taken of the recent visit of Lord Wolseley here, at the unveiling of the statue erected to the late General Earle, to secure his presence at a tournament held in the Liverpool Exhibition, in connexion with the National Physical Recreation Society. In distributing the prizes, his lordship said he did not think that there was any man in that great building at that moment who was more interested in athletics than he was. And he would tell them the reason why. It was because he believed that the first great necessity of man was health, and it was impossible that he could be healthy unless his body was thoroughly exercised and his muscles were kept supple and always in good working order. He could not help thinking that the good deeds and achievements that had been accomplished by the English people from time immemorial had arisen from the fact of their being a healthy and strong people. They might rest assured that men with flabby muscles, and poor, miserable constitutions never could be either the fathers of healthy children or even respectable citizens. The conditions of their life in England of late were very much changed from what they were in former times. In past generations people lived much more in the country than they did now. At this present period of the nineteenth century there was a tendency to crowd into large cities and towns, and he felt it to be the bounden duty of every man and woman and child interested in the future of England to do all that was possible to further the work of athletic instruction and to promote athletic sports. He had often thought what a great pity it was that the people who made the laws for them when they started that great scheme of education—which they did start, and which had worked such very great changes and benefits for the people of all classes in the community—did not couple their endeavours to educate the mind with some arrangement for educating and training the body. He hoped sincerely that the time was not far distant when they would have attached to every board school in the country a good drill sergeant, a good gymnast, a good gymnasium, and a good place where they could take exercise. He had been very much struck with what he had seen there that evening. That was the first time he had been in that hall, and he had wondered at its enormous size and the number of people that it held, and he could not help feeling what a loss it would be to the people of Liverpool if that building were ever allowed to be removed. Indeed, he could not help thinking that it would amount to a positive disgrace to the city if it ever allowed that magnificent building to be taken away from that place, and by doing so deprive the younger people of the possibility of going there to train, as all of them might. It was a hall which from its size alone was not only evidently intended for athletic sports, such as had taken place there that evening, but was also a hall where he was sure his friends the Volunteers would be very glad to go to parade and exercise and drill. He was told it could be had at a very small price. He therefore hoped the public spirit of the people of Liverpool would enable it to be purchased for the benefit of the Volunteer forces, and, above all things, for the benefit of those athletes. He wished them all a very good night, and was much obliged to them for the very cordial welcome they had accorded to him. He should carry away with him a very pleasant recollection of all he had seen, and only hoped that the success which had attended that meeting might be continued in the future.

THE POLICE AND NIGHT DUTY.

The night beat of the Liverpool police is from 9 P.M. till 5 A.M., and during the winter months this duty is very severe; but the men are only placed on it for short intervals, and while doing it they have the rest of the day at their disposal unless they are required in court. Many years ago an excellent arrangement was commenced, which has continued ever since, by which all the men on duty are enabled to go in detachments to the district bridewell between 1 and 2 A.M. Here facilities are ready for each man providing himself with hot coffee, thus causing an agreeable break in a long and often monotonous watch, and giving each man a wholesome stimulant to enable him to finish the remainder of his duty.

THE ROYAL INFIRMARY.

A special appeal for additional and increased donations towards the Royal Infirmary Rebuilding Fund has met with a very liberal response, and it is hoped that the whole of the required sum will be subscribed before the building is completed.

DRUG PROSECUTION IN LIVERPOOL.

A chemist was to-day fined five shillings and costs for selling sweet spirit of nitre which Dr. Campbell Brown certified to be completely decomposed by keeping.

MANCHESTER.

(From our own Correspondent.)

TECHNICAL EDUCATION.

THE movement for promoting technical education has been taken up warmly in Manchester, and at a public meeting held in the Town Hall, and largely attended by a very influential and representative audience, Professor Huxley gave a very eloquent and exhaustive address, setting forth the objects and aims of the present movement in this direction. On the same day a most munificent offer tending towards the same object was made to the city by the trustees of the late Sir Joseph Whitworth, who have purchased the estate on Oxford-road known as Potter's Park, at a cost of £47,000. This estate they are willing to hand over to the corporation as a gift, to be used as an open space and park for the use of the people; but they ask that there shall be provided on one part of the property a museum of commercial products and materials, an art gallery, and a technical school on a complete scientific and practical plan.

PURE AIR.

The Noxious Vapours Abatement Society and branch of the Sanitary Association deserve much credit for their persistent efforts to abate and reduce the smoke nuisance. Amongst the lectures lately delivered under their auspices have been one by Mr. A. E. Fletcher, chief Government inspector under the Alkali &c. Act, and another by Mr. Herbert Fletcher, a large manufacturer and user of steam power at Bolton. Ample evidence was adduced by both these very competent witnesses that the pollution of our atmosphere here and in other large manufacturing towns is entirely unnecessary. Mr. H. Fletcher gave details of the arrangements now in use at his own works, whereby the commonest kinds of coal can be burnt without producing smoke, to the gain of the consumer and relief from dirt of the surrounding inhabitants. Surely it is time that those charged with carrying out the law bestirred themselves more vigorously. Lately we have had a few more prosecutions of the worst offenders, but whilst they are permitted to escape with a fine of twenty or thirty shillings we shall not see much improvement in our murky, grimy atmosphere.

OWENS COLLEGE.

This College has lost by death another of its professorial staff. Professor Balfour Stewart, who since 1870 has held the chair of Physics, died at his residence near Drogheda on Monday, quite unexpectedly. His name is known to all scientists in connexion with the radiation and absorption of heat, and with the subject of terrestrial magnetism. He took considerable interest in the proceedings of the Psychical Society, but what his own opinions were with respect to the work and inquiries initiated by that body are not very clearly known. On Saturday night the annual soirée of the College Union took place in the College buildings, the attendance at which was very large. Scientific apparatus, experiments, drawings, music, and singing were provided for the entertainment and instruction of the visitors. The concert in the chemical theatre, given by some of the members and their friends, was very enjoyable.

CHEAP MEALS.

Another good work being done, and which has been aided to a great extent by the Sanitary Association, is the provision this winter of cheap meals for the poor school children. Operations were commenced last week, when dinners were provided in the Ancoats districts to a crowd of hungry children, at a cost of a halfpenny each, consisting of pea-soup and bread, and a slice of bread-and-jam. This charge of one halfpenny defrays the actual cost of food and cooking, but the expenses of labour, room, utensils, &c., have to be met out of voluntary subscriptions, and the committee ask for a sum of £500 to enable them to do what they at present contemplate.

HOSPITAL ACCOMMODATION IN SALFORD.

The provision of a new Fever Hospital for Salford is still anything but *un fait accompli*. In the meantime scarlet fever still prevails extensively, seventy to eighty fresh cases per week being reported in the two municipalities; and it was stated publicly very recently that the present Salford Hospital [illegible] Medical Officer of Health [illegible] Captain Nicholls that [illegible] the many thousands who have [illegible]

for preventing the spread of infection, will be prosecuted under the provisions of the Public Health Act, 1875. It is of interest to note that some of the smaller health authorities are taking a real interest in their duties in this respect, as the Local Boards of both Moss Side and Crumpsall have just lately passed a resolution expressing the desirability of obtaining further powers as to the control, supervision, and reporting of infectious disease at dairies and farms.

Dec. 20th.

NORTHERN COUNTIES NOTES.

(From our own Correspondent.)

SCARLET FEVER AT NEWCASTLE WORKHOUSE.

IT is stated in our papers that nearly 200 cases of scarlet fever have occurred in the Newcastle Workhouse during the last outbreak there, with a mortality of only about 1 per cent. It would be interesting to the profession to know how many cases have been marked by the usual sequelæ, and it is to be hoped that the medical officer will in time give us a history of this remarkable and, in many respects, exceptionable epidemic. It is stated that Dr. Mowat, acting under instructions from the Local Government Board, has just visited the workhouse to inquire and report upon the outbreak.

TYNE PORT SANITARY AUTHORITY.

At the annual meeting of this authority, held last week, the report of the inspector stated that during the past two months the inspection of vessels had been as follows:—British steamers 1233, British sailing vessels 461, foreign steamers 301, foreign sailing vessels 179, visits to fishing vessels 10, water boats 6, extra visits 486, grand total of visits 2676. In the great majority of cases where sanitary defects were found and orders given they were complied with.

WHITE-LEAD POISONING.

At a late meeting of the Gateshead Board of Guardians the subject of lead poisoning in female workers came up for discussion, and the following resolution was adopted: "That, having regard to the great burden cast upon the union by the manufacture of white lead, the victims of such work having to be maintained for a life-long period on account of their premature decrepitude, palsy, and blindness, inevitably resulting from the present modes of manufacture, we hope the Government will insist upon machinery being used in the most dangerous parts wherever practicable." It was stated during the discussion that the system resulted in a mortality of 25 per cent. in the female workers, in spite of all sanitary precautions usually taken in the best works. It was shown that one of the most dangerous stages of the manufacture was where the girls carried the white lead in the form of liquid from the pan to the store. The workers were in a state of perspiration, and the white lead was splashed about them and absorbed through their pores, and it was contended that no medical treatment could fully neutralise that effect.

DURHAM UNIVERSITY AND MEDICAL DEGREES.

The news that the two great Colleges in London were anxious to combine to give a medical degree [illegible] received here with much favour, but the project [illegible] received even a greater welcome had the Hall been [illegible] in the proposed arrangements. As might have been expected, however, the University of Durham is [illegible], and a convocation will be held in Bishop [illegible] Durham, to-morrow, for the purpose of [illegible] to the Queen against the proposal to [illegible] Colleges of Physicians and Surgeons of England [illegible] to confer degrees in medicine and surgery. [illegible] arrangements suit the University of Durham [illegible] nexions admirably, but it forgets that [illegible] most oppressive to the English student of [illegible] felt here that the step taken by the [illegible] is against the feeling of the times, as well [illegible] broad interests of the profession [illegible]

DRUNKENNESS IN [illegible]

Some exception has been taken [illegible] in my last letter as to drunkenness [illegible] been pointed out that there has [illegible] this year—according to the [illegible] Captain Nicholls that [illegible]

our Exhibition. This is quite true, and it speaks very well for our citizens, as well as for our visitors; but the point in my letter was directed against a certain and very large class of our working men, and we must fail to believe the evidence of our senses if we imagine that there is any diminution in intemperance or the many evils which spring from it amongst thesame class at the present day.

EDINBURGH.

(From our own Correspondent.)

TIME INCIDENCE OF CARDIAC MURMURS.

AT the last meeting of the Royal Society an important paper on the methods of determining the exact situation of murmurs in the cardiac rhythm, and their relation to the series of events forming one complete cycle of the heart's action, was presented by Dr. Byrom Bramwell and Dr. Milne Murray. Their investigation was an outcome of the recent discussion in the columns of the LANCET upon the exact significance of presystolic murmurs raised by Dr. Dickinson's paper upon the subject. The object of the present research was to determine at what stages of the cardiac movements the various sounds that accompany them really occur. The exact registration of the movements themselves is accomplished by the cardiograph; but an instrument of telephonic registration of the sounds is still a desideratum. In his remarks on this subject Dr. Bramwell stated that he had directed Mr. Edison's attention to this matter, and pointed out to him of what great value such an apparatus would be to the clinical observer in medical diagnosis. Failing the application of such an instrument to the solution of the problem, Drs. Bramwell and Milne Murray have in the meantime invented an apparatus that goes far towards surmounting the difficulty. While the cardiac movements are recorded graphically on a prepared surface of paper by the cardiograph, a time-recording apparatus marks the exact interval of time on the same, and in addition to this a third writing style, under the control of the observer, marks time to the rhythmically recurring sounds of the heart as he hears them through a flexible stethoscope with blindfolded eyes; thus being alike cut off from the misleading tactile impressions of the cardiac impulse and the concomitant visual impressions of the movements of the end of the stethoscope accompanying the movements of the chest wall. This record involves theoretically the "psychic loss" necessary to the sensori-motor activity on the part of the observer in hearing and recording the sounds conveyed to him through the stethoscope, and an interesting collateral series of experiments was performed for the purpose of ascertaining its equivalent expressed as a period of time. This preliminary observation, made with a seconds clock, which recorded its own beat, and had its concomitant ticking synchronously recorded by an observer as the cardiac sounds were recorded in the way described above, shows that this psychic loss is practically *nil*. After the observation had been continued for a short time the latent period due to the sensori-motor action of the observer became shortened, the nervous system, apparently becoming accustomed to the rhythmic impressions, conveys them more speedily, and the actual record of the clock's beat and that of the clock's tick, as heard and registered, were found to coincide precisely. Thus in a heart where the action is regularly rhythmic, the sounds produced in the rhythm can be recorded, after an interval of probation on the part of the observer, with absolute accuracy, and the result of this record compared with the reading of the movements recorded by the cardiograph; and any sound may be thus referred to its exact situation in the cardiac cycle. Taking a case of proved relationship in this respect, one of aortic regurgitation, it was found that the murmur was always registered exactly at that point in the cardiac cycle where its causative reflux is known to occur, showing that the method is reliable, and can be applied to the question so fully discussed recently as to where and how presystolic murmurs are occasioned. Into that question the observers have not as yet fully entered, but they hope to communicate further on the subject when a sufficient number of cases shall have come under their notice to furnish data for a reliable conclusion.

ABERDEEN.

(From our own Correspondent.)

HEALTH OF THE CITY.

FOR October, Aberdeen had the lowest death-rate of the eight principal towns in Scotland; but for November it did not occupy such a satisfactory position. For last month the death-rate was 20·4 per 1000, as compared with 19·2 in Leith and 20·2 in Edinburgh. There was a gratifying decrease in the number of cases of scarlet fever during November. In September there were 73 cases of scarlet fever, 114 in October, and 47 in November. Whooping-cough is on the increase; there were 68 cases reported in November, and during the present month 50 cases have already been reported. Since August there have been 22 deaths from whooping-cough, as against 16 from all the other zymotic diseases—viz., 1 from small-pox, 1 from measles, 10 from scarlet fever, 2 from diphtheria, and 2 from typhoid fever. In November there were 5 cases of typhus fever in St. Nicholas parish. There were 56 patients in the city hospital on Nov. 1st, and 40 were admitted during the month, making a total of 96; and of these 45 had been discharged and 1 died, leaving 50 in the hospital at the beginning of the present month.

THE MEDICAL OFFICERSHIP OF HEALTH.

Dr. Theodore Thomson, who has held the office of medical officer of health for the city since Dr. Simpson's appointment to Calcutta, was recently appointed medical officer for Sheffield. Lord Provost Henderson, at the Council meeting yesterday, expressed his regret that the city was "to lose the services of Dr. Thomson so soon, ... it looked as if Aberdeen were to be a nursery for the training of medical officers for other cities." At a meeting of the Public Health Committee held to-day, it was resolved to request Dr. M'Kenzie Booth to fill the office, *ad interim*, between the departure of Dr. Thomson and the appointment of his successor. For the vacancy, which is to be advertised, Dr. John D. Thomson is a candidate. Dr. Thomson has just returned from Berlin, where he had been studying under Professor Koch, and for some time after graduating he acted as assistant to Professor Ogston.

UNWHOLESOME FOOD.

During the month of November the sanitary inspector seized 890 lb. of beef, 177 lb. of mutton, 5417 lb. of fish, 78 lb. of fruit, and 132 lb. of vegetables, all of which were destroyed, either with the owner's consent or by order of the magistrates. There had been 458 inspections during the month.

DUBLIN.

(From our own Correspondent.)

THE EPIDEMIC OF MEASLES NEAR SKIBBEREEN.

AT a meeting last week of the Skibbereen Board of Guardians a communication was received from Dr. O'Farroll, medical inspector of the Local Government Board, in reference to the extensive and fatal epidemic of measles which has prevailed for some time in the Skibbereen district. It appears that the disease exists at Tullagh, on Hare Island, and at Baltinare. Measles was imported last September into Baltinare by a sailor returning from a training ship at Plymouth, and since then a very large number of cases have occurred through the Tullagh district, amounting to about 200, with some eighteen or twenty deaths. The deaths which have taken place have been for the most part among young children, and the mortality among them would seem to have been due not so much to any special malignity of the exanthem poison, as to the severity of those pulmonary affections which complicate measles, and which at this season of the year are often, even with the most favourable surroundings, of very serious import. But these children were nursed in a wretched room or cabin, so small that the air space is barely sufficient for a single person. In Hare Island eighteen families were affected with measles, with only one death. The water supply of this island is of a very bad kind, the water obtained from the wells by the inhabitants being constantly polluted by the excreta of cattle and other animals.

Digitized by Google

The consideration of the report has been deferred to the first week in January.

ROYAL COLLEGE OF SURGEONS.

In consequence of a petition to the Council from some students, that body have passed a resolution calling on the committee of management of the conjoint scheme to publish at once all necessary details as to the examinations. This was urgently required, as the students have not, up to the present time, been able to learn to what extent they were required to be prepared in certain subjects.

GALWAY COUNTY INFIRMARY.

A meeting of the governors was recently held to elect a resident surgeon to the hospital, in the room of the late Dr. Browne. The following were candidates:—Messrs. Mahoin, Lambert, Kinkead, Colohan, and Pye. Eleven votes were recorded for Dr. Colohan and four for Dr. Pye, the former being declared elected. As, however, nine of those who voted had only that day paid in £21 each, constituting them life governors, a protest was lodged against the reception of their votes as illegal and contrary to the Act. Should this view of the matter be correct, it follows that Dr. Pye will be elected; at all events steps are being taken to test the legality of the election.

CANAL-STREET DISPENSARY: SOUTH DUBLIN UNION.

A meeting of the South City Dispensary Committee was held to-day (Tuesday), to elect a successor to Dr. Ball, who had resigned his appointment as medical officer to the Canal-street Dispensary, which he had held for the past seven years. There were eleven applicants for the post, Dr. Falkiner being elected, subject to the sanction of the Local Government Board.

Measles is still prevalent in Dublin, and during the past nine weeks 116 deaths have been registered from this cause.

Dublin, Dec. 20th.

PARIS.

(From our Paris Correspondent.)

THE PURIFICATION OF WATER.

IT is now generally admitted that water plays a very important *rôle* in the production and propagation of epidemic maladies. To render water really innocuous two means are generally employed: (1) By antiseptics; (2) by ebullition. In a communication recently made to the Société Française d'Hygiène, M. Charles Tellier, an engineer, stated that the first means named is uncertain, and is not within the reach of everyone. The second is good, but it has the following inconveniences:—1. The temperature of 100° C. (212° F.) is not sufficient to destroy all the microbes. 2. The air of the water is expelled by the effect of ebullition, and the water becomes heavy and indigestible. 3. The calcareous carbonates are equally precipitated, and the water becomes less sapid. 4. The earthy portions in suspension in the water are also precipitated, and the latter is rendered disagreeable to drink. To obviate these different inconveniences, the author proposes the substitution of water submitted to a higher temperature for water which has been merely boiled, and the following is the manner in which this is effected. A closed metallic recipient, perfectly air-tight, being able to support a pressure of six atmospheres, is established. At the bottom this recipient presents an enlargement, which is calculated so that by the dilatation during the heating the water completely fills the recipient. A tap placed in the lower part, surmounted by a filter, permits the drawing off of the water; another tap placed in the upper part surmounted, at the moment of its employment, by a filter in cotton wadding, allows the air to enter. When the bottle is full of water, it is placed either in a bath saturated with marine salt, or in a recipient into which steam is admitted. In the one case, as in the other, it is heated, and the water is thus raised to a temperature varying from 114° to 150° C. The following are the results of this operation: — 1. The water remains perfectly aerated, as, having been heated without pressure, the air cannot separate itself, and remains dissolved. 2. The water remains charged with its calcareous salts, as the carbonic acid is not disengaged. 3. The other salts and earthy matters are precipitated, but they separate from the water at the moment of its employment, as a filter exists in the apparatus. 4. The filter is never contaminated, as it is itself baked at each operation. 5. In fine, the water remains purified during the whole time of its employment, as the air which enters into the apparatus is itself filtered by the cotton.

ANTIPYRIN.

For some time past Dr. A. Robin has been engaged in researches respecting antipyrin, so as to assign to it its proper place as a therapeutical agent, and the following are the conclusions arrived at by him, which he formulated in a paper he recently read before the Academy of Medicine: 1. Antipyrin acts at first on the nervous system, of which it modifies the excitability, not in a purely dynamical manner, but in acting on its elementary nutrition. 2. It diminishes organic disintegration, and lowers still more organic oxidations, whence the production of an excess relative to the lithic acid and to the nitrogenous extractive materials, which are less soluble, and consequently with more difficulty eliminable, than urea. It is probable that this influence on the general nutrition immediately depends on the effects of the antipyrin on the nervous system, as the depressing medicaments of nervous activity act nearly all in the same manner. 3. Antipyrin possesses also a powerful antiseptic property, which is very marked, and which appears to manifest itself as well in the organism, and without injury to it, as in the experiments in the laboratory. In a word, antipyrin acts in the first place on the nervous system, of which it moderates the excitability in modifying its elementary nutrition; it diminishes the organic disintegration and lowers still more the organic oxidations, and may for this reason be classed among the series of medicaments to which Professor Germain Sée has given the name of "*médicaments d'épargne.*" Its action as an antipyretic is *nil*, whilst against painful affections its action is well marked. Dr. Robin would therefore suggest that the name "analgésine" should be substituted for antipyrin.

Paris, Dec. 20th.

Obituary.

SIR GEORGE BURROWS, M.D., F.R.S.

BY the death of Sir George Burrows, which occurred in his eighty-seventh year, at his residence in Cavendish-square, on the 12th inst., another, almost the last, survivor of the old school of distinguished Cambridge graduates who adopted medicine as their profession has passed away. He came of an old Kentish family, established certainly as far back as the Commonwealth at Chalk, in the neighbourhood of Gravesend, where the birth, in 1771, of his father, Dr. George Man Burrows, himself an eminent member of the medical profession, took place. Sir George Burrows was born on November 28th, 1801, in Bloomsbury-square, where his parents then resided, and received his early education at a school at that time of some note in Ealing, where he had for his fellow-scholars several who afterwards distinguished themselves, amongst them being Cardinal Newman and Mr. F. W. Newman. On leaving this establishment Sir George attended the lectures of John Abernethy at St. Bartholomew's Hospital, of Professor Brande on chemistry, and of Professor Faraday on electricity and other kindred subjects. At the end of two years he proceeded to Caius College, Cambridge, where, although he had obtained a Tancred medical studentship, he devoted himself to the special study of that University, and graduated as tenth wrangler in the Mathematical Tripos of 1825. It may be mentioned that during his undergraduate days he organised and pulled stroke in the first six-oar racing boat that floated on the Cam. Immediately after his graduation he was elected a Fellow of his College, and appointed junior Mathematical Lecturer. He occupied much of his spare time in private tuition, and was a popular and successful teacher. However, he shortly afterwards returned to St. Bartholomew's Hospital, and, as a pupil of Sir W. Lawrence and Dr. Peter Mere Latham, who, with Sir Thomas Watson, formed at that time the leading lights of that famous school, commenced the systematic study of that profession he was in later years destined to so much adorn. After taking his degree in Medicine at Cambridge and the diploma of the Royal College of Physicians of

Digitized by Google

London, he availed himself of a favourable opportunity for foreign travel, and studied his profession for some time at the University of Pavia, in Paris, and in Germany. During his stay in Italy he had abundant opportunities for watching the epidemic of Asiatic cholera, then freshly imported into Europe; and upon its making its appearance in London in the year 1832, he was placed in charge of the auxiliary hospital established by the governors of St. Bartholomew's to meet the exigencies of the outbreak. This was his first official connexion with the institution. A little later, in 1834, he was appointed the first assistant physician, to take charge of out-patients. He first lectured on Forensic Medicine, and was subsequently associated with Dr. P. M. Latham as joint lecturer on the Science and Practice of Medicine. In 1841, upon Dr. Latham's enforced withdrawal from ill-health, he became sole lecturer, and was promoted to the full physiciancy, an office which he held with distinction till 1863, when he retired from the acting staff. On this occasion he was presented with a testimonial by his colleagues, and elected the first honorary consulting physician to the hospital. In 1832 he became a Fellow of the Royal College of Physicians, in which institution he subsequently delivered the Gulstonian, Croonian, and Lumleian lectures, in the latter of which he explained and illustrated experimentally the condition of the circulation in the brain under varying conditions of pressure. He filled in turn the offices of member of Council, Censor, College representative on the General Medical Council, and finally, in 1871, he was called by the unanimous voice of the Fellows to the presidential chair of the College, to which he was elected five times in succession. During his tenure of office as president—namely, in 1874—he was made a baronet. Having been appointed Physician Extraordinary to Her Majesty the Queen in 1870, he became Physician in Ordinary in 1873, on the death of Sir H. Holland. He was a member of the Senate of the University of London, president of the General Medical Council, of the Royal Medical and Chirurgical Society, and of the British Medical Association. Sir George was the author of a work on Disorders of the Cerebral Circulation, and the connexion between Affections of the Brain and Diseases of the Heart (the Lumleian Lectures in 1843-44), and of several articles in Tweedie's *Library of Medicine*. He was also a prominent member of the St. Albans Medical Society, of which he was at one time president. The composition of this Society was, and is, seven physicians, seven surgeons, and seven general practitioners. We believe that Professor Erichsen is at present president of the Society, which is so exclusive that one black ball suffices to ensure the rejection of a nominee for admission. Sir George Burrows was also a Fellow of the Royal Society, D.C.L. Oxon., LL.D. and Honorary Fellow of Caius College, Cambridge.

In 1834 Sir George married Elinor, the youngest daughter of his old master, John Abernethy. This lady predeceased him, but three children (two sons, and one daughter, married to Mr. Willett of St. Bartholomew's Hospital) survive him. Of commanding presence, Sir George invariably inspired confidence in his patients, and although he rarely smiled, and still more rarely laughed, he possessed a kindly heart and sympathetic mind, which caused his aid and advice to be frequently sought by those who knew him. Owing to his advanced age, he had of course for some years retired from practice, and to the younger school of medical men the name of our late *confrère*, who was a living link between the present and the giants of the past, is comparatively unknown. A correspondent who acted as his clinical clerk, and who now occupies a distinguished position in the metropolitan medical world, writes: "Next to Christison, ... I never knew in our profession a man of more solid worth and nobleness of character. He was a real leader of men, and a humble and devout Christian."

The funeral was held at Highgate Cemetery on the 17th inst., and perhaps there never was a more imposing private funeral ceremonial. The College of Physicians was represented officially by the senior Vice-President, Sir Edward Sieveking (nominated by the President, who was unable to attend), the senior Censor, Sir A. Garrod, and Sir Dyce Duckworth, treasurer, all wearing their official robes. Mr. Marshall represented the General Medical Council, Mr. Savory the Royal College of Surgeons, and Mr. Pollock the Royal Medical and Chirurgical Society; and the hospital staff of St. Bartholomew's Hospital were almost all present. The procession of carriages, nearly half a mile in length, included those of all the recognised leaders of the profession.

JOHN GEORGE FRENCH, F.R.C.S.

A LINK with the distant past has been broken by the death of this well-known surgeon, who expired suddenly on Dec. 4th, after attaining the ripe age of eighty-three.

Mr. French, who was born at Bow, Middlesex, on Oct. 13th, 1804, was the son of the Rev. William French, rector of Vange, Essex, and was educated at Christ's Hospital. Thence he proceeded to Worthing, where he served his apprenticeship with the late Mr. Morrell, a well-known medical practitioner in that town, and later entered as a student at Guy's. His teacher in surgery was Sir Astley Cooper—then in the zenith of his fame,—for whose scientific and personal qualities Mr. French always retained, in common with all the pupils of that great surgeon, a profound admiration. Having become L.S.A. in 1826 and M.R.C.S. in 1827, he was for a short time engaged in practice in Henrietta-street, Brunswick-square. In 1830 he succeeded in obtaining the post of surgeon to the workhouse infirmary of St. James's, Westminster, an appointment which he held for forty-two years. A considerable change has taken place in the administration of medical relief in the various parishes of the metropolis. For a great part of the time during which Mr. French held his post his duties not only embraced the charge of the workhouse and its infirmary, the latter including some sixty or eighty beds, but he had also, on the order of the relieving officer, to attend and provide drugs for the sick poor dwelling in various parts of the parish. The entire medical charge of the paupers was in his hands. The field of experience thus presented to a man of energy and ability was very great, and Mr. French availed himself of it very thoroughly. He proved to be a good surgeon and family practitioner in high estimation. In the year 1853 he became F.R.C.S. On his appointment to St. James's Infirmary, Mr. French at first resided in Marshall-street, Golden-square, removing in 1842 to 41, Great Marlborough-street, where he lived until 1872, the year in which he resigned his post. His last years were spent at 10, Cunningham-place, St. John's Wood.

The first outbreak of cholera in Great Britain occurred in 1831. The disease appeared in Sunderland in October, having been introduced by a vessel from Hamburg. When the metropolis was visited by the epidemic a cholera hospital was formed in St. James's, as in many other parishes, and Mr. French was appointed its medical officer. He threw himself into the duty with ardour, and employed the opportunities for the clinical study of the disease to such good purpose that a book published by him on the subject in 1835 attracted much attention from the philosophical style in which the subject was treated. In the autumn of 1848 the disease reappeared and persisted during 1849, giving further opportunities of study to Mr. French, and intensifying the enthusiasm which the subject always produced in him. Again appearing in 1853, the disease was signalised by an outbreak in the Soho district in the summer of 1854, which from its sudden and terrible mortality exceeded all experience of epidemic fatality in the metropolis since the time of the great plague. It was in this visitation that Mr. French became acquainted with the late Dr. John Snow, whose discovery of the conveyance of cholera by drinking water, first suggested by him in reference to an outbreak in South London, was confirmed by his investigations in the Soho outbreak, which he traced with unerring sagacity to a pump in Broad-street. Mr. French, who at first, like everyone else, was very sceptical as to the soundness of the position, became completely convinced by the demonstration afforded in this epidemic, and a most ardent promulgator of Dr. Snow's views. It was in this year that he published a second edition of "The Nature of Cholera Investigated," a work which, with occasional papers in the journals, served to create for him the position of an authority on the subject. His interest in this topic never failed, persisting even in his old age, in spite of the fact that it was not altogether reciprocated by those with whom he came in contact.

In 1862 Mr. French brought before the Royal Medical and Chirurgical Society a plan of treating carbuncle by a subcutaneous incision of its base, from which he had had excellent results, and which has scarcely received adequate recognition by surgeons. The paper was published in the *London Medical Review*, a periodical which has long been extinct. Although the subject of cholera was that which perhaps most strongly attracted him, he was fond of opera-

Digitized by Google

tive surgery, opportunities for which were very numerous in the public appointment which he held. He was one of the first to excise the hip joint, following the teaching of his friend Sir William Fergusson and Mr. Jones of Jersey.

There was a certain air of the old *régime* about Mr. French which even advanced age failed to destroy, though the profound deafness from which he suffered of late years necessarily left its mark upon him. In other respects he retained even to the day preceding his death a full command of his faculties, and time had not succeeded in destroying the bright and genial qualities which those who knew him in days gone by will well remember. He was a well-read man, not only in medical but in philosophical literature, and a lover of music and of art. His tall, well-set figure, endowed with a quite exceptional activity, as it was during the greatest part of his career, was a familiar object for many years in the hunting field, for, though a true-born cockney, he was amongst the most fearless of riders, and a great lover of horses. Of kindly nature, overflowing with animal spirits, and possessed of considerable sense of humour, Mr. French enjoyed, until his infirmity interfered, the acquaintance of a large circle of friends. The passage of time has removed very many of these, but there are still left not a few to cherish the memory of one who was a skilful practitioner of medicine and a good fellow. Mr. French was buried at Paddington Cemetery, Willesden-lane. He was never married.

THOMAS GOODIER RICHMOND, F.R.C.S.

The subject of the present notice, who died at his residence, Ford House, Prestbury, Macclesfield, on the 17th inst., aged seventy-seven years, was educated at the Manchester Grammar School, and his medical studies were pursued at the Manchester School of Medicine and Surgery, in Pine-street, and subsequently at the principal London hospitals. He became a Member of the Royal College of Surgeons and Licentiate of the Apothecaries' Society in 1833. He commenced practice in his native town in Gartside-street, and subsequently in Coburg-terrace, near Zion Chapel; but it was in the township of Hulme that Mr. Richmond became a popular medical practitioner and a foremost sanitary reformer. He had the entire medical care of the township during the prevalence of cholera in the summer and autumn of 1849, and of the Irish fever in 1851-2. Following the outbreak of cholera in 1849, he issued a report on the deplorable sanitary condition of Hulme. To this report on "Cholera and Choleraic Diarrhœa," no doubt, may be attributed the measures afterwards adopted to improve the water supply, drainage, badly constructed dwellings and lodging houses, &c. When Asiatic cholera reappeared in England, in September, 1853, nearly the whole of the medical men in Manchester, with Dr. Radford at their head, assembled and drew up a code of precautionary and preventive measures. Mr. Richmond co-operated with this movement, and furnished another valuable report to the authorities of his own experiences, and made suggestions which were acted upon. As a thoroughly practical sanitary reformer Manchester is much indebted to him. In 1854 Mr. Richmond was elected a Fellow of the Royal College of Surgeons. About this time he resided in the Chorlton-road, and carried on a large practice on that side of Manchester. He retired some years ago, and lived at Prestbury. In private life Mr. Richmond was a very agreeable, pleasant companion, and he possessed some literary ability.

FREDERICK THOMAS MARRIOTT, L.S.A.

THE above-named practitioner died somewhat suddenly on Nov. 18th, 1887, at 121, Old-street, E.C., aged fifty. Possessed of some private means, he was able to gratify his artistic tastes as a musician and connoisseur of bric-à-brac, and at the same time to avoid the harassing toils and anxieties which, alas, too frequently appertain to the daily round of the general practitioner. Educated at University College, he obtained his L.S.A. diploma in 1877; subsequently he held the posts of assistant house-surgeon to the Western General Dispensary, and assistant medical officer to the Lock Hospital and Salop Infirmary; he was also for some years trumpeter-major and bugler to two corps of Volunteers. A polished man of the world, and an ardent sympathiser with the poor, his memory will remain green in the hearts of many of his brother practitioners and the more indigent of his patients.

Medical News.

UNIVERSITY OF LONDON.—The following candidates have passed the recent M.D. Examination:—

Arkle, Charles Joseph, University College.
Bahadhurji, Kaikhosro Nasarvanji, B.S., University College.
Barnett, Lawrence, University College.
Bright, Eustace Frederick, University College.
Carr, John Walter, B.S., University College.
*Cocking, William Tusting, University College.
Davies, William Thomas Frederick, B.S., Guy's Hospital.
Dingley, Arthur William, University College.
Evans, Willmott Henderson, B.Sc., University College.
*Gow, William John, St. Bartholomew's Hospital.
Green, Charles David, B.S., St. Thomas's Hospital.
Halstead, George Ezra, B.S., B.A., B.Sc., Guy's Hospital.
Harsant, Joseph George, B.S., Guy's Hospital.
Hichens, Frank, B.S., London Hospital.
Hull, Walter, St. Thomas's Hospital.
Jefferson, Arthur John, B.S., St. Thomas's Hospital.
Joule, John Samuel, University Coll. and St. Barth. Hosp.
Lewtas, John, St. Thomas's Hospital.
Marsh, George Ryding, Guy's Hospital.
Paley, Frederick John, St. Bartholomew's Hospital.
Randell, Reginald Maurice Henry, Guy's Hospital.
Rayne, Charles Alfred, B.S., University College.
Robinson, Henry Betham, B.S., St. Thomas's Hospital.
Swain, James, B.S., Westminster Hospital.
Thomas, John Raglan, St. Bartholomew's Hospital.
Trevelyan, Edmond Fauriel, B.Sc., St. Bartholomew's Hospital.
Turner, Philip Dymock (Gold Medal), University College.
Washbourn, John Wychenford, B.S., Guy's Hospital.
*Wild, R. Briggs, Manchester Royal Infirm. and Owens College.
Williamson, Richard Thomas, B.S., Owens College.

Logic and Psychology only.

Thomson, St. Clair, King's College.

* Obtained the number of marks qualifying for the Medal.

The following candidates have passed the recent examination in subjects relating to Public Health:—

Collins, W. Job, M.D., M.S., B.Sc. (Gold Medal)[illegible] rivate study.
Pearce, W., M.D., B.S., B.Sc., St. Mary's Hospital
Smith, Kenneth Rawlings, M.D., B.S., University College.

UNIVERSITY OF DUBLIN.—The following degrees were conferred last week by the Chancellor of the University:—

BACHELOR IN OBSTETRICS.—William Payne Birmingham, Thomas Willoughby Cole, John Cuffey, Harry Fayle, Ernest Augustus Slaughter, Armstrong Herbert Swifte Todd, William James Weir, Charles William Henry Whitestone.

BACHELOR IN SURGERY.—Henry Kingsmil Abbott, William Payne Birmingham, Thomas Willoughby Cole, John Cuffey, Alfred Russell Darley, Edwin Lindsay Dunn, Charles Grey-Edwards, William Moyle O'Conner, Ernest Augustus Slaughter, Wm. James Weir.

BACHELOR IN MEDICINE.—William Payne Birmingham, Alfred Russell Darley, Frederick William Kidd, Ernest Augustus Slaughter.

MASTER IN OBSTETRICS.—George Chadwick Kingsbury (*stip. con.*).

DOCTOR IN MEDICINE.—Thomas Guy Alexander, Benjamin Morgan Dockerell, Frederick William Kidd, Joseph William Neligan.

ROYAL COLLEGE OF SURGEONS IN IRELAND.—At examinations held last week the following was admitted a Fellow of the College:—

Waller, Thomas Bennett.

THE polling for an Assessor for St. Andrews University has resulted in the success of Lord Cross and the defeat of Dr. John Duncan.

THE University of Douai has been removed to Lille, much to the regret of the inhabitants of the former city. The first University at Douai was established in 1560.

A NEW HOSPITAL has been erected at Ruabon by Sir Watkin Williams Wynn, at a cost of £2500. The building was formally opened on the 13th inst.

VACCINATION GRANT.—Mr. P. Butler Stoney, of the Millom district of the Bootle Union, Cumberland, has been awarded the Government grant for efficient vaccination in his district (fifth time).

AT the annual meeting of the supporters of the Royal Albert Hospital, Devonport, on the 13th inst., satisfactory financial and general reports were presented and adopted.

THE GORDON HOME FOR BOYS.—After having been, by permission of the War Office, quartered for nearly two years in one of the forts on Portsdown Hill, the Gordon boys have taken possession of their own home at Chobham.

MEASURES are being taken, we understand, to ascertain the views of the local authorities in Aberdeen and district on the question of erecting for their joint use a hospital for the treatment of persons suffering from infectious diseases.

Digitized by Google

SOME successful experiments were made at the Brown Institution on the 12th inst., as to the feasibility of saving life at sea by inflation of the skin after a method described in our columns some three years ago by Dr. Silvester.

CENTENARIAN.—Mrs. Mary Hodges of Elton, Hunts, whose death has just been recorded, attained her hundredth birthday on May 9th. She retained her faculties to the last. Her favourite beverage is reported to have been rum, and she was a habitual smoker.

THE New York Academy of Anthropology offers a prize of fifty dollars for an original essay on any subject within the domain of Anthropology. The competition is limited to active, honorary, and corresponding members of the Society at the time the award is made.

PRESENTATION.—On the 12th inst. Mr. Hedley Hill, a student at the Bristol General Hospital, was presented with the silver medal of the Royal Humane Society and an address on vellum, in recognition of the bravery exhibited by him in a successful attempt to rescue, on the 18th of October last, a woman from drowning in the Avon.

FATAL FOOTBALL ACCIDENT.—A young man belonging to Leeds was recently injured while playing in a football match at Roundhay-park, between the Trinity and Roundhay Clubs, and died at the Leeds Infirmary on Thursday last. It appears that he was knocked down and his head forced underneath his chest, so as to dislocate the cervical vertebræ.

MEASLES.—An epidemic of measles has made its appearance in Boston, and several deaths have occurred. The day and Sunday schools have been closed, and the medical officer of health has published a notice warning the parents of infected children not to attend places of worship or public entertainment. The disease is also very prevalent in the Western islands of Scotland and in Canterbury.

THE LADY STRANGFORD HOSPITAL.—It is satisfactory to learn that this institution at Port Said has now been in good working order for some months, and has been of service to many sufferers, who have been landed there from steamers passing through the Suez Canal. Last month 60·8 per cent. of the beds were filled. The committee appeal for £2200, which is still required for the building fund.

NORTH-WESTERN ASSOCIATION OF MEDICAL OFFICERS OF HEALTH.—A meeting of the members of this association was held on the 8th inst., Dr. Tatham in the chair, when a paper on "Infant Mortality in Urban Districts" was read by Dr. Welch. The paper, which was illustrated by numerous charts and tabular statements, elicited a discussion, in which Messrs. Niven, Kenyon, Vacher, Rhodes, and others took part.

BEQUESTS.—The following, amongst other legacies, have been given by the will of the late Mr. Thomas Jessop: The Jessop Hospital for Women, £4000; the Sheffield General Infirmary and the Sheffield Public Hospital, £200 each; and the Free Hospital for Children, £100.—The late Thomas Cochrane has bequeathed £200 to the Hospital for Incurables, £200 to the Mater Misericordiæ Hospital, £100 to St. Vincent's Hospital, and £50 to St. Michael's Hospital near Dublin.

THE ULSTER MEDICAL SOCIETY.—The annual dinner of this Society was held at the Royal Avenue Hotel on the 23rd ult. The President, Dr. Esler, occupied the chair, and was supported by a large and influential company. After the usual loyal toasts, the following were given: "The Belfast Medical School," "The North of Ireland Branch of the British Medical Association," "The Ulster Medical Society," and "Our Guests." The evening was enlivened by songs sung by several of the guests, and a very enjoyable *réunion* took place.

VICTORIA UNIVERSITY.—The following appointments to vacant examinerships were made by the Council at a meeting held on Dec. 15th:—Obstetrics: G. Ernest Herman, M.B., F.R.C.P., F.R.C.S., Obstetric Physician and Lecturer on Midwifery in the London Hospital. Pathology: Victor Horsley, M.B., B.S., F.R.C.S., Professor of Pathology in University College, London. Physiology: Augustus D. Waller, Lecturer on Physiology in St. Mary's Hospital Medical School, London. Surgery: A. Pearce Gould, M.B., M.S., F.R.C.S., Assistant Surgeon and Surgical Tutor at Middlesex Hospital, London. Anatomy G. D. Thane, M.D., Professor of Anatomy in University College, London. Forensic Medicine and Hygiene: G. V. Poore, M.D., F.R.C.P., Professor of Medical Jurisprudence in University College, London.

THE Sultan of Turkey has conferred upon Dr. Morris H. Henry of New York the decoration of Commander of the Order of the Medjidieh of Turkey, for "distinguished services in the cause of medical science."

MEDICAL MAGISTRATES.—Upon the recommendation of the Lord-Lieutenant, the Lord Chancellor has inserted the name of Mr. Vincent Jackson in the Commission of the Peace for the county of Staffordshire. Mr. Jackson was Mayor of Wolverhampton last year, and is also a magistrate for the borough.—Mr. David Lloyd, M.R.C.S., L.S.A., has been made a magistrate for the county of Cardiganshire.—The Lord Chancellor, upon the recommendation of the Lord-Lieutenant, the Earl of Dartmouth, has placed William Harry Cooke, M.D., of the Manor House, Aldridge, in the Commission of the Peace for the county of Stafford.

TELEPHONES IN HOSPITALS.—The authorities of the Hospital for Consumptives at Ventnor have decided to adopt telephonic communication between the different wards, the resident doctor, the porter's lodge, &c. The Equitable Telephone Association, Limited, of Queen Victoria-street, London, E.C., who have been entrusted with the order, will employ eleven of their "Swinton" telephones, and the instruments will be connected on the ordinary exchange principle, so that any one of them can be put in communication with any ther. It is anticipated that, when completed, this installation will save the hospital staff much time and trouble.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column are invited to forward it to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week for publication in the next number.*

ADDINSELL, AUGUSTUS W., M.B., C.M., has been appointed Administrator of Anæsthetics to the Grosvenor Hospital for Women and Children.

ALEXANDER, ADOLPHUS B., L.D.S., R.C.S. Eng., has been appointed Dental Surgeon to the Good Templar and Temperance Orphanage.

BARLOW, ARTHUR H., M.B., C.M., M.R.C.S., has been appointed Medical Officer to the Leicester Provident Dispensary, vice Douglas, resigned.

BROOMFIELD, H. J., L.K.Q.C.P.I., L.R.C.S.I., has been appointed Assistant Physician to the City of Dublin Hospital.

CARTER, GRAHAM ATHERLEY, M.D.Mar.Col.Aberd., L.R.C.S. Ed., has been reappointed Medical Officer of Health for the Lichfield Urban Sanitary District.

COWARD, R. COURTENAY, M.R.C.S., L.R.C.P.Lond., has been appointed Honorary Medical Officer to the Kilburn, St. John's-wood, and Maida-vale General Dispensary.

FERNIE, EDWARD, M.D. St. And., M.R.C.S., has been appointed Medical Officer for the Swynnerton District of the Stone Union.

GAMGEE, ARTHUR, M.D., F.R.S., has been elected Assistant Physician to St. George's Hospital, W.

MILNER, JAMES G., L.R.C.P. Ed., M.R.C.S., has been appointed Assistant Physician to the Home and Infirmary for Sick Children and Dispensary for Women, Sydenham.

PATTERSON, GEORGE HENRY, L.R.C.P.Lond., M.R.C.S., L.S.A., has been reappointed Medical Officer of Health for the Dalton-in-Furness Urban Sanitary District.

PLEWS, PAUL R., L.R.C.P.Ed., L.F.P.S.Glas., has been appointed Medical Officer for the Fourth District of the Parish of St. Matthew, Bethnal-green.

SAUNDERS, CHARLES EDWARD, M.D.Aber., M.R.C.P.Lond., San.Sc.Cert. Cantab., has been reappointed Medical Officer of Health for the Watford Rural Sanitary District; for the Hendon Rural Sanitary District; for the Hemel Hempstead Rural Sanitary District; for the Berkhampstead Rural Sanitary District; for the Barnet Rural Sanitary District; for the Tring Urban Sanitary District; for the Welwyn Rural Sanitary District; and for the Barnet Urban Sanitary District.

SNELL, WALTER STANNES, L.R.C.P.Ed., L.R.C.S., has been appointed Medical Officer of Health for the Okehampton Rural Sanitary District, vice Bennett, deceased.

STEELE, HENRY OCTAVIUS, M.R.C.S., L.S.A., has been reappointed Medical Officer of Health for the Gomersall Urban Sanitary District.

THOMSON, JOHN M., F.R.S. Ed., has been appointed Professor of Chemistry at King's College, London, vice Bloxam, deceased.

TURNER, GEORGE R., F.R.C.S., has been elected Assistant Surgeon to St. George's Hospital, W.

WATSON, THOMAS ALFRED, M.B., C.M.Edin., has been appointed House-Surgeon to the Central London Ophthalmic Hospital, vice M. C. Moxham, M.R.C.S., L.R.C.P., resigned.

WEDMORE, ERNEST, M.B. Cantab., M.R.C.S., has been appointed Obstetric Physician to the Bristol Royal Infirmary.

WILDING, JAMES, M.B., L.R.C.P., M.R.C.S., C.San.Sc., has been appointed Medical Officer to the Bristol Foresters' Institute.

WYNNE, J. DARLEY, B.A., M.B., B.Ch.Trin.Col.Dub., has been appointed Junior Assistant House-Surgeon to the Public Hospital and Dispensary, Sheffield.

Digitized by Google

Vacancies.

In compliance with the desire of numerous subscribers, it has been decided to resume the publication under this head of brief particulars of the various Vacancies which are announced in our advertising columns. For further information regarding each vacancy reference should be made to the advertisement.

ADDENBROOKE'S HOSPITAL, Cambridge. — Resident House-Physician. Salary £65 per annum, with board, lodging, and washing in the hospital.

BOOTLE CORPORATION HOSPITAL FOR INFECTIOUS DISEASES.—Resident Medical Officer. Salary £100 per annum, with board, washing, and apartments at the hospital.

CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST, Victoria-park, E.—Resident Medical Officer. Salary £100 per annum, with board, &c.—Resident Clinical Assistant.

ESSEX AND COLCHESTER HOSPITAL. — Physician. Salary £200 per annum.

FARINGDON UNION.— Medical Officer, Public Vaccinator, and Medical Officer of Health. Salary £70 per annum, with extra fees for operations and services allowed under the orders of the Local Government Board, together with the statutable vaccination fees.

GLAMORGANSHIRE AND CARNARVONSHIRE INFIRMARY AND DISPENSARY, Cardiff.—House-Surgeon. Salary £100 a year, with board, washing, and furnished apartments.

HOSPITAL FOR SICK CHILDREN, Great Ormond-street, W.C.—Junior Resident Medical Officer as House-Surgeon. Salary £50 per annum, with board and residence in the hospital.

HULL ROYAL INFIRMARY.—Junior Assistant House-Surgeon. Salary £50, with board and lodging.

MONSALL FEVER HOSPITAL, Manchester.—Assistant Medical Officer. Salary £100 her annum, with board and residence.

NATIONAL DENTAL HOSPITAL, Great Portland-street, W.—Lecturer on Histology.

POPLAR HOSPITAL FOR ACCIDENTS, East India-road, Poplar, E.—Two Honorary Surgeons.

ROYAL FREE HOSPITAL, Gray's-inn-road, W.C. — Junior Resident Medical Officer. Board and residence in the hospital.

ST. GEORGE'S HOSPITAL, Hyde-park-corner, W.—Curator of the Pathological Museum.

ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN. — Two Assistant Physicians.

WIGAN UNION.—Medical Officer, Public Vaccinator, and Dispenser. Salary £170 per annum, unfurnished residence and surgery, free of all rates and taxes, and coals, together with the usual allowance for each case of successful vaccination, and such extra fees for the treatment of surgical and midwifery cases as are authorised by the orders of the Poor Law Board.

WORCESTER AMALGAMATED FRIENDLY SOCIETY. — Assistant Medical Officer. Salary £140 per annum (without residence), with a portion of midwifery fees; also £20 per annum for cab hire.

Births, Marriages, and Deaths.

BIRTHS.

CROOKSHANK.—On the 15th inst., at The Yews, Eastbourne, the wife of Edgar Crookshank, M.B., of a daughter.

CROOM.—On the 16th inst., at 25, Charlotte-square, Edinburgh, the wife of J. Halliday Croom, M.D., F.R.C.P.E., of a daughter.

DOWNES.—On the 19th inst., at Mellerstein, Eastbourne, the wife of Dr. H. Downes, of a son.

GLENDINNING.—On the 15th inst., at Larchfield, Abergavenny, Monmouthshire, the wife of James Glendinning, M.D., Medical Superintendent, Joint Counties Asylum, Abergavenny, of a daughter.

MCGEAGH.—On the 12th inst., at Oakford, Polsloe-road, Exeter, the wife of Surgeon R. T. McGeagh, Army Medical Staff, of a son.

SAWTELL.—On the 8th inst., at Stapleton-hall-road, Stroud-green, N., the wife of T. H. Sawtell, M.D.Lond., M.R.C.S., L.R.C.P., of a son.

THOMSON.—On the 18th inst., at Coates-crescent, Edinburgh, the wife of John Thomson, M.B., C.M.Edin., of a son.

TIBERGHIEN.—On the 20th inst., at 52, Rue du Nord, Brussels, the wife of Lucien Tiberghien, M.D., of a son.

UPPLEBY.—On the 16th ult., at Port Elizabeth, South Africa, the wife of Dr. J. G. Uppleby, of a daughter.

WARNER.—On the 16th inst., at Rydal, Woodford-green, Essex, the wife of Percy Warner, M.R.C.S., L.R.C.P.Lond., of a son.

MARRIAGE.

CRIPPS—BRADLEY.—On the 15th inst., at St. Matthew's Church, by the Rev. A. H. Baynes, assisted by the Rev. T. B. B. Ferris, Vicar, Charles Couper Cripps, M.D., of Denmark-hill, London, son of Richard Cripps, of The Grove, Brislington, Somerset, to Edith Ellen, only daughter of John Bradley, of The Park, Nottingham.

DEATHS.

GARDEN.—On the 17th inst., at The Cedars, Merrow, near Guildford, Archibald MacDonald Garden, Deputy Surgeon-General, Bengal Medical Service, retired, and late Superintendent-General Vaccination, Punjab, in his 56th year.

TOLEKEN.—On the 13th inst., at Longford-terrace, Monkstown, co. Dublin, John Toleken, M.D., Ex-Senior Fellow of Trinity College, Dublin, in his 85th year.

N.B.—*A fee of 5s. is charged for the Insertion of Notices of Births, Marriages, and Deaths.*

Notes, Short Comments, & Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

All communications relating to the editorial business of the journal must be addressed "To the Editors."

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news-paragraphs should be marked and addressed to the Sub-Editor.

Letters relating to the publication, sale, and advertising departments of THE LANCET *to be addressed "to the Publisher."*

We cannot undertake to return MSS. not used.

THE CLIMATE OF EGYPT.

DR. SCHLIEMANN, the celebrated archæologist, having gone outside his *métier* to disparage the climate of Egypt in relation to phthisis, has evoked from Dr. Heymann (for many years the leading German physician in Cairo) a highly effective rejoinder. Egypt, according to this eminent authority, remains what she always was—a supremely favourable winter resort for the consumptive patient in every stage of his malady. Dr. Heymann furnishes evidence that in the two requisites of a winter station for the phthisical the advantages of the Egyptian climate are pre-eminent, the first requisite being the obviating of the disposition to tuberculosis of the lung, or the correcting of this at its early stage; the second, mitigation of the distressing and wasting symptoms of the disease when advanced.

Private Practitioner.—There is no written law on the subject, and the medical officer of health cannot therefore be said to be acting illegally; but it is customary for him to obtain his information through the medical attendant, whose certificate on this subject should guide him.

F. C.—1. Fee quite reasonable.—2. Not too much, if the patient can pay. Rental small for that.—3. A guinea.—4. A guinea. The patient is liable, not the medical man.

Dr. A. G. Macdonald.—We cannot advise in the matter.

WORD-DEAFNESS AND WORD-BLINDNESS.

To the Editors of THE LANCET.

SIRS,—In the various works which treat of word-deafness and word-blindness the description of these defects is so confused as to be scarcely intelligible. They are, I believe, supposed to be due respectively to lesion of the first and second temporo-sphenoidal convolutions, and of the angular gyrus and adjoining part of the inferior parietal lobule; but I am not clear whether these defects are due solely to lesions in the left hemisphere, as in motor aphasia. Is this so? Information on this point will be much appreciated by,

Yours faithfully,

Dec. 19th, 1887. A MEMBER OF TWENTY YEARS' STANDING.

P.S.—Is hemianopsia due to lesion of the same centre as word-blindness?

*** The part of the brain concerned in the auditory perception of words is the posterior half of the first temporal convolution on the *left* side in right-handed individuals; so is the centre for word-blindness. Hemianopsia may be due to a cortical lesion.—ED. L.

VIVISECTION.

THE *Globe* of Dec. 19th publishes the following letter:—

"*A Correction.*—Sir,—In your issue of Nov. 30th there was a short report of a speech of mine at the Anti-Vivisection Conference held the day before, in which I related an incident that had been told me by a doctor, which implied a breach of the Vivisection Act by the University College, Liverpool. At the request of the College authorities, I have still further investigated the evidence on which I made my statement, and which I believed to be perfectly accurate at the time. I now find that my recollection of what I was told was not correct in certain respects, and that therefore the impression I conveyed to my audience was wrong. Consequently, I desire to withdraw the statement; and as your paper was the only one in which I saw it published, I shall be obliged if you will insert this note.—I am, &c., "WALTER S. B. M'LAREN.

"St. James's Lodge, Delahay-street, Westminster,
December 17th."

Mr. Hubert Henry, and *C. C.* (Chichester).—We must refer our correspondents to a paragraph on the subject published in THE LANCET of Oct. 15th, p. 794.

Fairplay.—It would, we think, be far better to endeavour to arrange a meeting with the view of settling the matter amicably.

J. S. S.—The course suggested is certainly open to objection.

V. V.—Our correspondent is thanked.

VOLUNTARY BOARDERS IN ENGLISH LUNATIC ASYLUMS.

To the Editors of THE LANCET.

SIRS,—I observe in your issue of the 17th inst. the reply of Dr. Savage to the question which you were good enough to allow me to put to your readers in THE LANCET of Dec. 10th. Having since I wrote taken the opportunity of consulting the Lunacy Acts upon the matter in question, I find the first part of that reply perfectly satisfactory, being, as I believe, in accordance with the provisions of 25 and 26 Victoria, cap. iii., sec. 18. But with regard to the second part of the reply—viz., "that registered hospitals, such as Bethlem, can receive as voluntary boarders any patients [i.e., those who may not have been within five years immediately preceding certificated patients in any asylum, hospital, or licensed house, or under care as certificated single patients] who voluntarily place themselves under care, provided," &c., I have failed to find any clause in any of the existing Lunacy Acts at my disposal bearing upon it. I should feel greatly obliged if Dr. Savage or some other of your readers would kindly point out this clause, if it should happen to exist in some other Act which I have not seen, and at the same time state whether such provision extends to English licensed houses, and also whether, both in the case of hospitals and licensed houses, the previous assent in writing of two or more of the Commissioners in Lunacy is necessary before admission as a voluntary boarder under it.

I am, Sirs, your obedient servant,

Dec. 19th, 1887. QUÆRENS.

ROUGH-AND-READY SURGERY IN THE BUSH.

To the Editors of THE LANCET.

SIRS,—A friend in New South Wales, writing in July last, mentioned that on returning from an excursion he had made on Jubilee day to the Sugar Loaf mountain he passed an old man sitting at the door of his hut sewing up with a needle and thread a rather severe cut he had inflicted on the thick part of his hand with a hatchet. In a letter written in October he gives an amusing sketch of an attempted cure for snake-bite:—"The other day a man came to me to be treated for snake-bite. A snake had bitten him on the point of the thumb, and he, wishing to cut a slice off, got an old razor, which he held against the place, his wife trying to hit it with the back of a knife, in which attempt she succeeded after striking his fingers several times. An incision being made, he at last got a piece off, partly tearing and cutting, and then came to me, a distance of ten miles. I kept him here under treatment for four hours, and then, finding there was no further danger, sent him home. I expect he will lose a piece of his thumb, but think the joint will be saved. It will not, however, prevent his working. People often maim themselves unnecessarily. I knew a girl who some time ago chopped her finger off with a tomahawk after snake-bite. As long as the teeth-marks are taken out about the size of a threepenny or sixpenny piece, that is quite enough."—I am, Sirs, yours truly,

New Cross, S.E., Dec. 7th, 1887. B. CARLILE.

EPSOM COLLEGE.

To the Editors of THE LANCET.

SIRS,—I have read with much concern the letter of "A Medical Practitioner" in your last issue relative to Epsom College. Having meditated sending two of my sons to the College, with the hope of securing a good education at a moderate outlay preparatory to entering upon the medical curriculum, I am staggered at the prospect of £150 a year for tuition fees. My income is insufficient for such an outlay, and I must therefore abandon the idea of this school, much to my regret. It becomes an impossibility for the average medical man to avail himself of the benefits of Epsom College for his boys at such an expense.

Believe me, Sirs, faithfully yours,

Dec. 19th, 1887. A GENERAL MEDICAL PRACTITIONER.

THE HISTORY OF BLIND ASYLUMS.

A. J. B. (Hamburg).—The best authority on this subject is M. Léon Legrand, from whose "Recherches sur la Condition des Aveugles du Moyen Age" we gather that in the first centuries of our era the blind were treated like the poor and infirm, St. Laurence, for example, having, according to the Church legend, tended a blind man in the house of Narcissus. St. Jerome, writing to St. Pammachius, enjoins him to seek equality with the poor, to be an arm to the weak and an eye to the blind. St. Basil founded at Cæsarea, about the middle of the fourth century, a hospital in whose *personnel* there were "leaders of the blind," which shows that the institution harboured those deprived of sight. In the fifth century St. Linnæus retired to a mountain, where the blind were brought to him for cure, and inhabited dwellings constructed around his hermitage. A century later Jerusalem could boast of a "typhocomium," and in the ninth century the Mahometans made tendance of the blind a State duty. In 1260 St. Louis instituted the hospital of the Quinze-Vingts, not, as is believed, to accommodate 300 knights who had been made sightless by the Saracens during the sixth crusade, but, according to Joinville, to give relief to the blind of Paris. This establishment harboured 300 blind of both sexes, who shared their means in common and lived together under the style of brothers and sisters, its director being nominated by the King, whose high almoner safeguarded its interests. Thanks to donations and contributions from all France, it acquired important possessions; and in 1292 Renauld Barboult, a burgess of Chartres, founded in imitation of it, at the gates of that town, another asylum called the Six-Vingts. Caen, Meaux, Châlons, Orléans, Tournay, and probably Angers, had each their "maison des aveugles," similar to which were the blind asylums of neighbouring countries. Vienna had one in 1223, Padua another in 1377, Frankfort another in 1489. In England the Guild of the Virgin was a mutual assistance society against maladies, particularly that of blindness.

Mr. W. H. Pepler.—1. We believe the report of the German Vaccination Commission was signed by the whole Commission. They were not unanimous on all points.—2. In 1882 vaccination was not obligatory in Austria, but was "carried out as far as practicable." In the same year in France vaccination was not compulsory on the general population, but short regulations existed requiring its performance on members of the army and navy. We believe no changes have been made in the laws of these countries since that date.—3. The extract is a fair *résumé* of Dr. Creighton's observations; but he states that he does not mean a venereal chancre.

Boxer.—We do not notice communications unauthenticated with the name of the writer.

X. Y. Z.—We do not give medical advice. The ordinary medical attendant should be consulted.

M.B.—Thanks. The reply appeared in our last impression.

THE MEETING OF CONSTITUENTS OF THE HOSPITAL SUNDAY FUND.

To the Editors of THE LANCET.

SIRS,—I fear that I must have expressed myself ambiguously at the meeting of the Hospital Sunday Fund at the Mansion House, as there is an error in your report. I did not say that if "twenty years ago the accounts of Guy's Hospital had been overhauled by the critical eyes of the Council the hospital would not be in its present plight," but I pointed out that if the accounts had been published for the last twenty years the liberality of the public would probably have prevented the hospital from being in its present plight. The accounts have been drawn up accurately, not merely for twenty years, but for a very much longer period. They have been regularly submitted to the Charity Commissioners, and now that the governors have appealed for public money they will be published. It is not bad bookkeeping, but agricultural depression, that has caused the vacant beds. The whole body of chartered accountants cannot raise the value of agricultural land. I trust that you will find room for this correction, and that Guy's Hospital may meet with that support from the Hospital Sunday Fund and from the public which its great necessities require and its careful administration unquestionably deserves.

I am, Sirs, yours faithfully,

Westbourne-terrace, W., Dec. 20th, 1887. ALFRED L. COHEN.

"A WARNING."

To the Editors of THE LANCET.

SIRS,—In your issue of to-day Sir Dyce Duckworth is good enough to warn members of the profession against a man who is using his name and recommendation to sell "various kinds of cloth." I expect this is the same person who called on a distinguished London surgeon a few days ago, and sent in my card as an introduction to business. He succeeded in selling a piece of cloth, and my friend will not grieve over the purchase if he can find a tailor to "make it up." I know nothing of this man, or how he got possession of my card.

I am, Sirs, very faithfully yours,

Manchester-square, W., Dec. 17th, 1887. WILLIAM H. DAY.

Medical Diary for the ensuing Week.

Monday, December 26.

ROYAL LONDON OPHTHALMIC HOSPITAL, MOORFIELDS.—Operations, 10.30 A.M., and each day at the same hour.
ROYAL WESTMINSTER OPHTHALMIC HOSPITAL.—Operations, 1.30 P.M., and each day at the same hour.
CHELSEA HOSPITAL FOR WOMEN.—Operations, 2.30 P.M.; Thursday, 2.30.
ST. MARK'S HOSPITAL.—Operations, 2 P.M.; Tuesday, 2.30 P.M.
HOSPITAL FOR WOMEN, SOHO-SQUARE.—Operations, 2 P.M., and on Thursday at the same hour.
METROPOLITAN FREE HOSPITAL.—Operations, 2 P.M.
ROYAL ORTHOPÆDIC HOSPITAL.—Operations, 2 P.M.
CENTRAL LONDON OPHTHALMIC HOSPITALS.—Operations, 2 P.M., and each day in the week at the same hour.

Tuesday, December 27.

GUY'S HOSPITAL.—Operations, 1.30 P.M. and on Friday at the same hour. Ophthalmic Operations on Monday at 1.30 and Thursday at 2 P.M.
ST. THOMAS'S HOSPITAL.—Ophthalmic Operations, 4 P.M.; Friday, 2 P.M.
CANCER HOSPITAL, BROMPTON.—Operations, 2.30 P.M.; Saturday, 2.30 P.M.
WESTMINSTER HOSPITAL.—Operations, 2 P.M.
WEST LONDON HOSPITAL.—Operations, 2.30 P.M.
ST. MARY'S HOSPITAL.—Operations, 1.30 P.M. Consultations, Monday, 2.30 P.M. Skin Department, Monday and Thursday, 9.30 A.M.
ROYAL INSTITUTION.—3 P.M. Sir Robert Stawell Ball: The Sun. (Lecture adapted to a juvenile auditory.)

Wednesday, December 28.

NATIONAL ORTHOPÆDIC HOSPITAL.—Operations, 10 A.M.
MIDDLESEX HOSPITAL.—Operations, 1 P.M.
ST. BARTHOLOMEW'S HOSPITAL.—Operations, 1.30 P.M.; Saturday, same hour. Ophthalmic Operations, Tuesday and Thursday, 1.30 P.M. Surgical Consultations, Thursday, 1.30 P.M.
ST. THOMAS'S HOSPITAL.—Operations, 1.30 P.M.; Saturday, same hour.
LONDON HOSPITAL.—Operations, 2 P.M.; Thursday & Saturday, same hour.
GREAT NORTHERN CENTRAL HOSPITAL.—Operations, 2 P.M.
SAMARITAN FREE HOSPITAL FOR WOMEN AND CHILDREN.—Operations, 2.30 P.M.
UNIVERSITY COLLEGE HOSPITAL.—Operations, 2 P.M.; Saturday, 2 P.M. Skin Department, 1.45 P.M.; Saturday, 9.15 A.M.
ROYAL FREE HOSPITAL.—Operations, 2 P.M., and on Saturday.
KING'S COLLEGE HOSPITAL.—Operations, 3 to 4 P.M.; Friday, 2 P.M.; Saturday, 1 P.M.
CHILDREN'S HOSPITAL, GREAT ORMOND-ST.—Operations, 9 A.M.; Saturday, same hour.

Thursday, December 29.

ST. GEORGE'S HOSPITAL.—Operations, 1 P.M. Ophthalmic Operations, Friday, 1.30 P.M.
CHARING-CROSS HOSPITAL.—Operations, 2 P.M.
NORTH-WEST LONDON HOSPITAL.—Operations, 2.30 P.M.
ROYAL INSTITUTION.—3 P.M. Sir Robert Stawell Ball: The Moon. (Lecture adapted to a juvenile auditory.)

Friday, December 30.

ROYAL SOUTH LONDON OPHTHALMIC HOSPITAL.—Operations, 2 P.M.

Saturday, December 31.

MIDDLESEX HOSPITAL.—Operations, 2 P.M.
ROYAL INSTITUTION.—3 P.M. Sir Robert Stawell Ball: The Small Planets. (Lecture adapted to a juvenile auditory.)

Lectures
ON
FIBROID DEGENERATION AND ALLIED LESIONS OF THE HEART, AND THEIR ASSOCIATION WITH DISEASE OF THE CORONARY ARTERIES.

By JOHN LINDSAY STEVEN, M.D.,
ASSISTANT TO THE PROFESSOR OF CLINICAL MEDICINE IN THE UNIVERSITY OF GLASGOW; ASSISTANT PHYSICIAN, GLASGOW ROYAL INFIRMARY; AND ASSISTANT TO THE LECTURER ON PATHOLOGY IN THE WESTERN INFIRMARY OF GLASGOW.

LECTURE III.

(*Concluded from page 1257.*)

CASE 9. *Fibroid degeneration of the left ventricle; pericardial adhesions; probably caused by embolism of the coronary artery.*—The specimen from this case is in the museum of the Western Infirmary of Glasgow; and the following is the account contained in the museum catalogue:—

"The extreme left lateral part of the left ventricle was found adherent to the pericardium over a limited area by somewhat elongated fibrous connexions. This part of the wall of the ventricle is converted into fibrous tissue, the muscular substance being almost completely replaced. This transformation extends through the entire wall, and affects a bulky papillary muscle, which is almost entirely fibrous. The affected portion of the ventricle is distinctly bulged outwards. Examination of the coronary arteries showed no obstruction, but the capillaries in the affected region are greatly diminished, as shown by injection of soluble Prussian blue. The heart as a whole is much enlarged, weighing 22 oz., and there is a deep groove between the two ventricles, producing a double apex. The aortic valve is considerably thickened, and the auriculo-ventricular orifices dilated. There was thrombosis in the veins, and pulmonary infarctions, &c.

"The origin of the fibrous transformation here is not perfectly clear, but it has probably originated in embolism of a small branch of the coronary artery, the circulation having been restored by anastomoses after the muscular tissue had already suffered softening. This is rendered the more probable by the fact that there were old embolic lesions in the spleen and kidneys, and the endocarditis of the aortic valve afforded a source of embolism when it was in the acute stage."

CASE 10. *Extensive fibroid degeneration of left ventricle, with pericardial adhesions; slight atheroma of left coronary artery; the lesion in this case inflammatory in origin (interstitial myocarditis).*—Janet B——, aged thirty-eight, died in Dr. James Finlayson's ward on June 2nd, 1887. On admission there was œdema of the ankles and eyelids, with considerable ascites. The urine was scanty, and contained abundant albumen and numerous granular tube-casts, but no blood. There was tenderness on pressure over the liver. The heart sounds were normal, and there was dulness with moist râles at both bases posteriorly. The illness had been of seventeen months' duration, and had been marked throughout by weakness and frequent inclination to faint. Swelling of the abdomen and ankles first supervened in October, 1886. The appetite had all along been bad, and vomiting occurred at intervals.

Summary of post-mortem: Considerable ascites; spleen firm, enlarged, weighing 8 oz.; deep cicatricial furrows on surface of liver, which on section present fatty areas; hepatic tissue generally fatty; organ weighs 3 lb. 7½ oz.; kidneys small, with adherent capsules, granular surfaces, and atrophied cortices; both lungs firmly adherent and œdematous. The heart is not greatly enlarged; the mitral orifice passes three, and the tricuspid four, fingers. On the anterior surface of the left ventricle near the apex, over an area of about two inches in diameter, there are firm fibrous pericardial adhesions. The muscular tissue immediately beneath the adherent surface is converted into a pearly white succulent tissue, which involves almost its entire thickness. On slicing the muscular tissue, similar patches, less extensive and evidently more recent, are found in the external and posterior walls of the left ventricle. An examination of the coronary arteries shows that, as a general rule, they are healthy and pervious; in the descending branch of the left, however, there is a very distinct patch of atheromatous thickening, which causes considerable narrowing of the lumen of the vessel. With this exception, however, no abnormality was discovered in the arteries. The wall of the aorta is practically healthy. A careful microscopic examination of this case proves it to have been distinctly inflammatory in origin. The new fibrous tissue was abundantly infiltrated with leucocytes, and at the margins of the patches the muscular fibres were separated by numerous leucocytes. This, then, seems to be an undoubted case of interstitial myocarditis, which has probably extended from the pericardium. Here and there the infiltration of leucocytes was very dense, obscuring the muscular tissue. Evidences of syphilis were present in the liver, and the unhealthy coronary artery should also be borne in mind in thinking of etiology.

CASE 11. *Slight fibroid degeneration with generalised fatty degeneration; atheromatous disease of the coronary arteries, with complete obstruction of the left at its origin.*—John Y——, aged forty-eight, died in Dr. Finlayson's ward on June 6th, 1887. He complained of a dull aching pain in the chest, which varied in severity, and which set in with an angina-like attack eighteen months before admission. When serving in India he had suffered severely from ague, and up till six years ago he had been a heavy drinker and smoker. The apex beat was displaced to the left of the nipple line, and could be felt in the sixth, seventh, and eighth interspaces. At the apex there was a loud blowing murmur with the first sound. There were signs of passive congestion.

Summary of post-mortem: Dilated heart with fibroid change; obstruction of one coronary artery; atheroma of aorta. The pericardium contained a small, and both pleural cavities a considerable, quantity of clear fluid. The heart was much enlarged, weighing 19 oz., the enlargement preponderating in the right ventricle. The aortic and pulmonary valves were competent. The left ventricle was considerably dilated, and its walls were thin; its endocardium was obviously thickened, and the muscular tissue was interspersed with tendinous patches. There was atheroma of the right coronary artery, and the orifice of the left was completely obliterated, while that of the right was also somewhat narrowed. The valvular curtains were not much thickened.

In this case the fibroid change was not extensive, and the patches were tolerably recent. On microscopic examination the usual replacement of muscular fibre by fibrous tissue was seen. There was also a slight but generalised molecular fatty degeneration of the muscular fibres. The left coronary artery was quite shut off from the aorta, but its walls were not seriously diseased. The right coronary artery was considerably dilated, even to its terminal branches, which largely supplied the posterior wall of the left ventricle. No arterial anastomosis between right and left could be discovered by tracing out the vessels.

CASE 12. *Rupture of left ventricle; serious disease of coronary arteries, with occlusion of the branches of the left passing towards the seat of rupture.*—Richard M——, aged sixty, a boat-hirer from Dunoon, was admitted to Ward 5 of the Western Infirmary, suffering from eczema of fifteen months' duration, affecting the face, neck, and body. At the time of his death, which occurred as follows, the disease of the skin, as the result of treatment, was almost completely cured. On the morning of Sept. 14th, 1884, he had gone as usual into the bath-room of the ward with his pot of ointment to anoint the skin. He was absent from the ward for about half-an-hour, during which time no one had seen him, and he was found lying quite dead at the foot of the bath-room stairs, his pot of ointment standing on the last step, where he had evidently laid it on feeling faint. He had been in his usual health up till the time of death, and had never at any time made any complaint to lead to an examination of the state of the heart.

On Sept. 16th I conducted a post-mortem examination, of which the following is a careful record:—External appearances: The body is well-nourished and muscular, and almost the entire skin is discoloured by a tarry preparation which had been applied for a somewhat generalised eczema. On the right temporal region and right side of the forehead are several contusions. Chest: The lungs are highly œdematous, but otherwise not abnormal. Heart: On opening the peri-

Digitized by Google

cardium a large quantity of blood-red serum escapes, and on evacuating this a large mass of clot, weighing about three-quarters of a pound, is found moulded on the surface of the heart. At the free margin of the left ventricle, midway between the auriculo-ventricular septum and the apex, is found a linear ragged aperture, measuring fully an inch in length, and lying in the long axis of the ventricle. Beneath the pericardium surrounding this opening, and extending towards the front of the organ, there is considerable hæmorrhage; and on the anterior aspect of the left ventricle, about an inch from the septum and an inch from the apex, is a distinct depression of a cicatricial appearance. The ragged aperture, before mentioned, communicates with the interior of the ventricle by a much smaller opening situated to the left of and behind one of the large fleshy masses, to which several of the tendons of the mitral curtains are attached. On section, the muscular tissue of the left ventricle in the neighbourhood of the rupture, and underneath that portion of the surface the seat of subpericardial hæmorrhage, is discovered to be exceedingly disintegrated. The tissue is soft, and presents a yellowish colour; so advanced is this in some situations that a condition of liquefaction is present. In some places, too, distinct cavities or channels exist in the heart wall, from which a brownish-coloured juice may be expressed in small quantity. The valvular structures of the left side of the heart are normal. The left coronary artery is highly calcareous, and is more or less completely occluded by atheromatous deposits. About one inch from its origin, and at a point beneath which it divides into two pretty large branches, is a distinct aneurysmal dilatation filled with soft clot. The branches leading from the aneurysm pass to supply the diseased portion of the ventricular wall, and are exceedingly hard and practically occluded. The right coronary artery is much dilated and tortuous, and here and there has a rigid feeling, but is nowhere obstructed. The external fat of the organ is generally somewhat exaggerated in amount, and encroaches very largely upon the tissue of the right ventricle. The valves of the right side, with the exception of some dilatation of the tricuspid orifice, are not abnormal. The whole organ is very soft and flabby, and weighs 15¾ oz. There is slight, but not at all extreme, atheroma of the aorta. The other features of the post-mortem are unimportant, and it only remains to note the condition of the kidneys. They are somewhat enlarged, and weigh respectively 6 oz. and 7½ oz. The surface of both is distinctly granular and lobulated, the capsule adhering with a moderate degree of firmness; and in some situations the demarcation between pyramid and cortex is not very clear.

Portions of the wall of the left ventricle were hardened first in alcohol and then in chromic acid, after which they were subjected to a very careful microscopic examination—the sections having been cut with Schanze's (of Leipzig) microtome. The first point that strikes one in looking at the sections is the interpolation, if one may so speak, amongst and between the muscular fibres of a granular tissue, which is in many places distinctly associated with the course of the bloodvessels, and which often interrupts the continuity of the muscular fibres and breaks them up. In very many parts of the section the transverse markings of the muscle are distinctly preserved, but in others they are lost, and the muscular substance has apparently become hyaline or glassy. Here and there a very slight granular fatty condition of the fibre is observed, but nowhere is this at all decided or extreme. In some sections the fatty growth on the surface of the heart seems rather increased, but in no situation does it extend deeply into the cardiac tissue. Staining of the sections in a 2 per cent. solution of gentian violet in water brings out the appearances just described much more distinctly. It is then well seen that the new formation of granulation tissue is situated immediately external to the fibres—in the perimysial tissue—and this is observed both in transverse and longitudinal section of the fibres. Where the cell proliferation is very abundant the fibres are largely destroyed, and, in addition, what appear to be the nuclei of the muscular cells are seen to be actively proliferating, as if they also were partaking in the process. Where the cell proliferation is abundant, too, the cells seem to be lying in a homogeneous transparent matrix, which is coloured neither by the chromic acid nor the gentian violet. In one of the stained sections the relationship of the new growth to obstructed vessels is distinctly observed. I refer to the appearance presented by a large artery, whose internal coat was so thickened as to leave only a very small lumen, and immediately outside of which the changes I have described were very extensive. The effect of the growth on the myocardium seems to be to cause the fibres to atrophy, to split up into longitudinal fibrillæ, and to lose their transverse striæ. Under the high power the cells comprising the interstitial new growth are, for the most part, seen to be of the nature of leucocytes, but where the change is very advanced much larger cells are observed, and a careful examination of stained specimens indicates that these are in all probability nuclei of the muscle cells.

CASE 13. *Rupture of left ventricle; extensive calcareous disease of coronary arteries; occlusion of the branch of the left passing towards the rupture.*—The specimen in this case was sent to the Western Infirmary museum by Dr. Yellowlees, of Gartnavel Lunatic Asylum, and was obtained from the body of a woman seventy years of age, who had been long insane. She was apparently in her usual state of health till she sank suddenly on the floor shortly after the usual weekly warm bath, and died almost immediately.

There is a large irregular aperture of a generally oval shape, and an inch long in diameter, situated in the anterior wall of the left venticle close to the septum. The wall of the heart is somewhat bulged around it, and the edges of the aperture are everted. There is no valvular disease. A careful dissection of the coronary arteries shows that both are the seat of very extreme calcareous disease, and that a large branch of the left going towards the rupture is quite impervious, being plugged by a thrombus. Under the microscope very distinct fatty degeneration of the muscular fibre is observed. But this change is by no means extreme, being entirely confined to the centre of the cell in the neighbourhood of the nucleus, and is certainly not sufficient of itself to have caused a spontaneous rupture of the muscular tissue; with this exception, however, the changes observed in this case are very similar to those described in the account of the last case, and so need not be dwelt upon at any length. It may be mentioned, however, that the main point of difference between this case and the last seems to be that the affection is more chronic—i.e., the cellular infiltration is not quite so abundant, and the development of fibroid tissue somewhat greater. Essentially, however, the changes in the two cases are the same.

CASE 14. *Rupture of the left ventricle; serious disease of the coronary arteries, with great obstruction of branch supplying ruptured area.*—The specimen in this case was sent to me for examination by my friend Dr. John Love, of the Royal Asylum, Gartnavel. It was obtained from a managed seventy-nine, who had been several times a patient in the asylum, and who was again convalescent from an attack of acute mania, so that he was to have been discharged in a few days. He was seized with severe præcordial pain in the morning while asleep in bed. When seen he was cold and blue; the pulse was rapid, feeble, and irregular; and the cardiac sounds were very distant and feeble. The first attack abated somewhat, but about 5 P.M. of the same day he had another, and died in an hour and a half.

At the necropsy the pericardium was found filled with thin bloody serum, while around the heart itself was a layer of clot. A small rupture was found in the anterior wall of the left ventricle close to the septum, and about two inches above the apex. The fatty envelope of the organ was much increased, and the wall of the right ventricle was very thin. The wall of the aorta presented almost no trace of disease, but both coronary arteries were very seriously affected. The descending branch of the left coronary was rigid in almost its whole extent. About an inch and a half above the level of the rupture several transverse thickenings were observed, which slightly narrowed the lumen of the vessel. At the level of the rupture the calibre of the vessel was very considerably diminished by the presence of a thick calcareous concretion about one inch in length, which could be shelled out from between the coats of the vessel. The right coronary was also exceedingly calcareous. No detailed or microscopic examination of the muscular tissue of the organ was possible, as very considerable decomposition had set in before I received it.

CASE 15. *Extreme fatty and slight fibroid degeneration; complete occlusion of right and partial of left coronary artery; extreme atheroma of the aorta.*—Arthur B—, aged sixty-three, a carter, was admitted to Dr. Finlayson's ward on Nov. 24th, 1886, with attacks of pain across the front of the chest and shooting to the back and down

Digitized by Google

both arms, of twelve months' duration. During the last ten weeks the symptoms were more severe, and were accompanied by considerable flatulence. The heart sounds and the cardiac area were normal; there was no cough or spit; the respiratory murmur was fairly good; the temperature was normal; and there was no albuminuria. He suffered from diarrhœa and melæna six years before his death, and from slight rheumatism which never laid him up.

Summary of post-mortem: Extreme atheroma of the aorta; complete occlusion of the orifice of the right coronary artery; partial obstruction of the left; thickening and incompetency of the aortic curtains; calcification of the middle coat of the femoral artery. It is unnecessary to record the report by Dr. Coats in detail, but I may simply refer to one or two of the more important points. There was the most advanced fatty degeneration of the heart muscle; and the musculi papillares presented very distinct tendinous transformation. On microscopic examination there is seen to be a very extensive fatty degeneration of the muscular fibres; in addition, where the fatty condition is less distinct, there is a clear translucent appearance presented by the muscular fibres, which in these places are devoid of transverse striæ. On testing the anastomoses with soluble Prussian blue, it is found that the pervious coronary artery communicates with the impervious somewhat freely. This is determined in the case of a branch situated close to the obstructed end; this branch is distributed to the right auricle, and it communicates freely with a branch of the other artery distributed to the left auricle. It is also determined that the branches distributed to the ventricles communicate.

CASE 16. *Generalised fatty degeneration; occlusion of one coronary artery, with narrowing of the other; atheroma of the aorta.*—John C——, aged thirty-six, a dock labourer, was admitted on Nov. 22nd, 1886, to Dr. Tennent's wards, complaining of shortness of breath and cough. Six months before he had been seized with a weight in the chest on exertion and palpitation, which were soon followed by cough and spit, tinged with blood. He died suffering from extreme orthopnœa, with œdema and dropsy. There were distinct ventricular-systolic and ventricular-diastolic murmurs over the sternum, with displacement of the apex downwards and to the left.

Summary of post-mortem: Atheroma of the aorta; complete occlusion of one coronary artery, narrowing of the other; thickening and partial destruction of aortic curtains; general venous hyperæmia. The general facts of the necropsy were similar to those recorded in connexion with the last case. Injection with soluble Prussian blue showed pretty free communications between the two arteries, and the fluid did not return by the veins. Communications were determined for the auricles and ventricles. The cardiac muscle presented the typical mottled appearance of fatty degeneration, especially that of the right ventricle.

The injection experiments described in connexion with the last two cases were carried out by Dr. Joseph Coats at the time of the post-mortem examination. Soluble Prussian blue is practically as thin as water; and hence such an experiment is liable to the objection I have previously urged, that with a thin fluid we can fill the other artery by means of the capillary or arteriolar (?) anastomoses. Therefore, unless the anastomosing branches can be actually traced with the naked eye, such an experiment does not refute Hyrtl's assertion that the coronary arteries do not anastomose by means of their primary and secondary branches.

In the foregoing lectures I have endeavoured to demonstrate the intimate etiological relationship existing between disease or obstruction of the coronary arteries, and certain lesions of the myocardium, especially fibroid degeneration, and to make it plain that the terms "chronic interstitial myocarditis" and "fibroid degeneration" (pure and simple), are not synonymous terms. I have also in the course of the lectures shown that multiple embolic lesions of the heart-wall may play a most important part (which should never be overlooked) in determining the clinical course of certain cases of valvular disease of the heart. Since the publication of my first lecture, Dr. Quain has kindly directed my attention to the articles on Connective Tissue Hypertrophy and Fibroid Disease of the Heart in the Dictionary of Medicine. The subject matter of the former article, which is by Dr. Quain himself, has scarcely come under consideration, as it refers to a general increase of the connective tissue of the whole organ; but in reading it I observe that the inflammatory theory stated in the Lumleian Lectures has been departed from. "This, and similar cases," he writes, "exhibit no appearance of chronic inflammatory action, and thus differ altogether from examples of that form of fibroid degeneration which is described under a separate heading (see Heart, Fibroid Disease of)." In the latter article by Dr. Mitchell Bruce, we have a most careful exposition of the subject of fibroid disease. The atrophic nature of the lesion and its association, in some instances, with degenerative changes in the vessels are pointed out. The term "fibroid disease," however, is still regarded as synonymous with chronic myocarditis; and the inflammatory theory of the affection seems, on the whole, to predominate in the writer's mind.

Clinical Lecture

ON

A METHOD OF EXCISING THE TONGUE.

BY RICHARD BARWELL, F.R.C.S,

SENIOR SURGEON, CHARING-CROSS HOSPITAL.

GENTLEMEN,—I removed seventeen days ago the tongue of this patient, and in a few more days he will leave the hospital cured. I will give you immediately a short history of his case, but firstly I call your attention to the fact that since the operation the man has had no high temperature, has been able to take food easily, and—remark especially this—he has virtually had no pain. All these advantages are attributable to the mode of operation which I devised and perfected about seven years ago. You saw me perform it, and will remember that it was almost entirely bloodless—a very great and decided benefit, more especially when the disease has caused difficulty in taking food, and therefore debility.

The method is this. Strictly in and along the middle line an opening is made about one-third of an inch long immediately in front of the hyoid bone, through the raphé of the mylo-hyoid. The genio-hyoid and genio-hyoglossus muscles are separated with the handle of the scapula until the deep surface of the mucous membrane forming the floor of the mouth is reached. By means of Liston's needles carried under this membrane to, or even beyond, the last molar teeth, threads are passed on each side into the buccal cavity, which in their turn draw flexible wire-twist,[1] first into, then out of, the mouth, in such wise as to surround the base of the tongue as far back as one will. An écraseur working with this wire severs that part of the organ. Then the loop of another écraseur is passed between the teeth, pressed well down on the first incision, and divides the structures beneath the tongue.

In this way then, I operated on Aug. 6th on George G——, aged forty-seven, who had a large epithelioma on the left side of the tongue, behind its middle; the induration, however, extended very far back and across to the other side of the organ. No enlarged glands could be felt. The ulcer was extremely sensitive: eating and even swallowing caused pain and trouble to him, while the very foul condition of the mouth took away all desire for food. During the operation but very few drops of blood were lost. Very soon after recovery from the anæsthetic he wrote on the slate that he was pretty comfortable.—Aug. 8th: There had been a copious flow of saliva and other secretion from the supra-hyoid wound. The patient daily took a large quantity of milk and beef-tea, with, he says, more ease than he had done for a long time. The wound was frequently syringed and the mouth rinsed with a 1 in 60 solution of carbolic acid, and the breath was hardly at all tainted.—24th: On the 16th the man could comfortably eat finely minced meat, and had gained flesh since the last report.—30th: He left the hospital, the tongue wound being firmly cicatrised on the 27th. He was able to eat very well, and for the last ten days had been able to enunciate with considerable distinctness.

I may also allude to another of my cases operated on in the same way, and which one or two of you, I believe, saw. It was that of a gentleman, aged fifty-one, who had in the

[1] See my paper in the Clinical Society's Transactions, vol. xiv., p. 147.

Digitized by Google

early part of 1885 a large epithelioma unusually far back in the tongue; he also had an enlarged gland close to the jaw, and about the middle of its body. After excising the tongue, therefore, I made an incision over the suspicious gland and removed it; this wound healed rapidly, and did not, I think, retard convalescence, which was rapid, enabling him to sit in an easy chair on the ninth day. Throughout this case also the stump of the tongue was painless. No sign of recurrence has shown itself.

Let me explain this painlessness, and point out certain other advantages of this operation—viz., its bloodlessness and its great security against septic pneumonia. The former of these is, I conceive, a very great gain. Three or four drops of blood come from the skin of the supra-hyoid wound, and only enough should be produced from the tongue to stain slightly the saliva. It is, however, right that I should tell you of an objection that has been urged against this procedure—viz, that if in the first section by the écraseur any considerable hæmorrhage should occur, the bleeding vessel would be inaccessible, the tongue being yet in the mouth. The matter, however, lies entirely in the hands of the surgeon, for the fact is that unless the écraseur be worked with culpable rapidity there is never any bleeding worth mentioning, since no large vessels are here divided. Moreover, the tightening of the écraseur wire produces that very compression of the base of the tongue which Mr. Heath has shown can be effected by two fingers introduced into the pharynx, and which he points out will check hæmorrhage. I have operated by Whitehead's and by Baker's method, and have more often seen those operations performed. One of my objections to both is that an unnecessary amount of blood is lost. The former method especially requires a particularly good light, and a patient quiet under anæsthesia, and able to open widely the jaws—a condition not by any means always present. Moreover, neither of these operations provides for draining the cavity; therefore foul saliva and pus accumulate at its back and in the fauces, is even apt to dribble down the larynx, and at least infects the passage through which the breath passes to the lungs. In my operation the supra-hyoid wound forms, if the patient's head be slightly raised, the funnel-like bottom to a cavity perfectly drained through that opening. I have never found it followed by septic pneumonia, and am glad to hear my patients complain, as they always do, that the mouth is dry. It has also been urged that this method does not provide for excising diseased glands. Well, that is true both of this and of the other two procedures I have mentioned. Superficial glands must be removed separately; the only plan which is adapted for the removal of the tongue and of deep glands is Kocher's exceedingly severe operation.

And now about the painless condition of the stump. The chief, if not the entire, tactile sensibility of the tongue is derived from the gustatory branch of the fifth, for this sense in the glosso-pharyngeal twig is very dull and obscure. The lingual gustatory reaches the tongue by passing down on the ramus of the lower jaw, and division of it in that part of its passage is a device for rendering the organ insensitive. Now the first cut of my écraseur divides these nerves from the point where they leave the jaw, or more often the wire does not cut them, but isolates them, leaving them as branched white threads loose in the mouth, in which case they are to be snipped off with scissors close to the bone; either way the stump has no sensory nerve, and thus is painless, to the great comfort of the patient.

YORKSHIRE ASSOCIATION OF MEDICAL OFFICERS OF HEALTH.—The annual meeting of the members of this Association was held at Huddersfield on the 22nd inst., when the twelfth annual report was read and adopted. The election of officers resulted as follows:—President, Dr. Britton, of Harrogate; vice-presidents, Drs. T. W. Hime, S. W. North, and J. S. Cameron; Dr. Giddings, treasurer; Dr. Wilson, secretary; and the committee as before, with the addition of Dr. Wade. Drs. Hime and Low were thanked for their services as president and treasurer during the year. Dr. Cameron read a paper on "The Relations between the Meteorological Conditions and the Respiratory Death-rates in Huddersfield during the past eight years." A discussion, in which several members joined, followed, and the meeting then closed.

AT a meeting on the 16th inst. of the Gloucester Saturday and Sunday Hospital Collections Committee, it was announced that £334 was available for distribution.

NOTES ON THE

TREATMENT OF SOME OF THE FORMS OF DISEASE INVOLVING THE AORTIC VALVES.

BY ARTHUR ERNEST SANSOM, M.D. LOND., F.R.C.P.,
PHYSICIAN TO THE LONDON HOSPITAL; CONSULTING PHYSICIAN TO THE NORTH-EASTERN HOSPITAL FOR CHILDREN; HONORARY FELLOW OF KING'S COLLEGE, LONDON.

(*Concluded from p. 1263.*)

I NOW propose to consider the treatment to be adopted in the cases of disease at the aortic outlet which are induced by atheroma—aortitis deformans. In these there is no history of acute or subacute rheumatism, the subjects are, in the great majority of cases, over forty years of age, and the disease has been of slow development, with no notable signs to mark its onset. In some cases there may be some difficulty in determining whether or not there has been an anterior endocarditis of rheumatic origin, for, as I have said, this affection may develop without arthritic or other signs of acute rheumatism. Generally, however, the differentiation presents no difficulty, for there are evidences of degenerative and senile changes, the arteries are hard and tortuous, the temporals are prominent and cord-like, and, except at the later stages, the pulse possesses nothing of the Corrigan (water-hammer) character, but manifests high tension; in fact, presents the characteristics so ably described by the late Dr. Mahomed.[1] Sometimes we are able to trace by clinical observation the course of the affection as it involves the aortic outlet. For instance, I had the opportunity of observing a gentleman, aged fifty-three, in whom symptoms of enfeeblement, fluttering of heart, and gradually increasing dyspnœa had been coming on for two years. He was the subject of gout, and generally had three attacks a year. The early observations of his heart showed the systolic murmur at the base of aortic obstruction. The pulse was typically one of high tension. Under treatment by alkalies and digitalis (in the form of the leaves) there appeared to be much improvement, and the general rate of the pulse was reduced from 104 to 60. Six weeks after the first observation an attack of gout occurred, and a slight diastolic murmur at the base became evident in addition to the systolic. There was no albuminuria. The diastolic murmur became more and more pronounced, the conditions of distress aggravated, and the patient died about five months after the first observation. This is, I consider, a fair type of a certain section of the cases. In some there is a very distinct association with chronic *renal disease*: in others with gouty arthritis or with conditions associated with lithæmia; in others with syphilis.

As in the rheumatic division, there may be evidences of considerable morbid change at the aortic outlet, and yet symptoms referable to the circulation may be entirely absent. I was consulted in May, 1878, by a gentleman aged thirty-eight for a painful condition of the nature of gouty arthritis, first about the right knee and afterwards the right hip. There was no complaint whatever of disorder of circulation or respiration, but a loud systolic and diastolic murmur at the base of the heart, with signs of hypertrophy, indicated considerable aortic disease. This gentleman had come from India on furlough, and returned to India to his duties in the Civil Service. I was consulted by him again on Sept. 2nd, 1886, after his return from India, where he had passed the intervening time, for pain referred to the soles of the feet. There was increased hypertrophy of the heart, with the former signs of aortic disease, but no symptoms whatever of cardiac difficulty; indeed, the patient looked upon it as a sort of folly that his heart should be examined, and insisted that I had not done so on the former occasion. My notes taken at the time verified the fact. In this case, therefore, there was advanced disease at the aortic orifice, with compensatory hypertrophy, which to my own knowledge had been in existence more than nine years without causing symptoms.

The unequal distribution of distress and danger in this form of aortic disease is shown by the histories of two cases

[1] Cf. Guy's Hospital Reports, vol. xxiv., 1879, p. 394.

Digitized by Google

lately under my observation almost contemporaneously. In both gentlemen the age was nearly identical—about sixty-five years; in both the physical signs were almost alike, evidencing obstructive and regurgitant conditions at the aortic outlet, with considerable hypertrophy of the heart. In one case no direct history of syphilis was obtained, but the tongue showed such losses of tissue that the affection at some remote anterior period was probable. This gentleman was exceedingly careful and temperate in his habits; he was nursed with affectionate solicitude; but, after passing through a period of much suffering, he died within two years of the manifestation of the disease. In the other case there was not only an undoubted history of remote syphilis, but an acknowledgment that the disease had been again contracted recently. The old man drank gin and whisky to the extent of at least a pint a day—probably much more. There were considerable dyspnœa and pain; but, after a few weeks' rest in bed, with a course of digitalis, recovery from all urgent symptoms took place, and the self-willed old gentleman is now apparently in very fair health, frequently in the open air pursuing his own course, and certainly not restrained by any theoretical notions of morality. Morbid anatomy, I think, enlightens us as to the cause of these seeming inconsistencies. In the aorta near the valves there may be much atheromatous change, and yet but little interference with the nutrition of the heart; but if the situation of a patch of atheroma be such that the orifice of a coronary artery is blocked, or if the vessel is obstructed in any part of its course, then efforts to promote a better ventricular force are unavailing. The præcordial pain and distress are the cry of a heart that cannot be nourished.

As to treatment. Supposing it be recognised that there is a change at the aortic outlet inducing obstruction or regurgitation, or both, and that this is associated with high tension in the arterial system, with sphygmographic evidence of a broad tidal wave, and so of effort on the part of the left ventricle, are agents which augment the force of ventricular systole to be withheld? According to my interpretation of the evidence afforded by my cases, certainly *not*. It is precisely in such that digitalis, caffeine, and convallaria are singularly beneficial, and the objections which I have so strongly urged against digitalis in the treatment of the purely rheumatic form of disease at the aortic outlet have little or no force. It is important, however, to be remembered that these objections have to be reasserted in the *advanced* conditions of atheromatous disease, when the orifice has become so distorted that regurgitation is very free. In most of the cases of aortic disease due to atheroma digitalis may be administered for long periods. It may seem, if we look at the conditions superficially, that it is illogical when the evidence indicates high tension in the arterial vessels to administer an agent which shall augment the tension, but further consideration will show that theory consorts with practice. The danger is not so much the augmentation of ventricular force, as the failure of the muscle of the ventricle to rise to the height of its requirements and so to enter upon its retrograde course of degeneration. Its more perfect systole, as brought about by the cardiac tonic, means not only a better propulsion of the blood through the obstructed terminals, but a better supply through the coronary arteries to its own structure. The only objections to digitalis in this form of disease are when it *(a)* increases the *suddenness* of the ventricular contraction, or *(b)* induces a notable perturbation of rhythm, such as the pulsus trigeminus—objections rarely manifested in the atheromatous, though often asserted in the rheumatic, form.

To supplement or supplant digitalis, caffeine is often very valuable. In cases attended with the appearance of much lithic acid or lithates in the urine, caffeine citrate in five-grain doses three times a day causes free diuresis, an increased elimination of solids, and great general improvement. In this dose the drug should not be continued more than three or four days, but one dose of five grains may be given every evening. So much relief from suffering is thus afforded that it is sometimes difficult to persuade the patient to omit the dose occasionally for a night or two. I am convinced, however, that such occasional omission is desirable: the change of one form of cardiac tonic for another is often very beneficial; I have seen great improvement when convallaria has followed digitalis.

I turn now to the evidence concerning agents of an opposite character—cardiac depressants. For the treatment of pain having the characters of angina, nitrite of amyl by inhalation, and nitro-glycerine, in solution or in tablets, are agents of the highest value; there is nothing to add to the valuable evidence of Drs. Brunton and Murrell on this point. It may, however, be an important matter for consideration whether these agents may be administered continuously for long periods. In some cases manifesting high arterial tension without evidence of valvular disease, I have seen great advantage from long-continued courses of nitro-glycerine. Often very small doses—1-200th gr. thrice daily—suffice to keep all adverse symptoms in abeyance. In the case of a female patient of mine, aged fifty-six, manifesting aortic obstruction and regurgitation but very high arterial tension, I allowed the administration of nitro-glycerine tablets for five months. For seven weeks the administration of 1-100th gr. twice a day was attended with the complete removal of all symptoms of distress; then, pain occurring, three instead of two doses were administered daily. Great improvement followed for nearly two months, when rapidly fatal œdema of the lungs occurred. In this case there were chronic renal disease and marked albuminuric retinitis. The necropsy showed acute nephritis engrafted upon the chronic. There was an atheromatous lesion of only one aortic cusp, and the left ventricle was hypertrophied. It can hardly be doubted that the immediate cause of death was renal rather than cardiac, and it is probable that the influence of the drug was wholly beneficial. I can conceive that it could be baneful, however, if regurgitation had been more free, or if there had been great and increasing obstruction of the coronary circulation; at any rate, I am sure that a caution is necessary to patients who are entrusted with a prescription for nitro-glycerine, for I have had evidence that as there is a morphinomania, so also there may be a nitro-glycerinomania. In March, 1885, I was consulted by a gentleman, aged sixty, who manifested signs of considerable dilatation of heart without murmurs, associated with copious excretion of urates. He had previously consulted a friend of mine, who, for præcordial pain, had, in a careful manner, prescribed nitro-glycerine

FIG. 8.

tablets. The patient found relief, and at every little discomfort swallowed a tablet. At the time he consulted me he was taking from six to twelve a day, probably more. He complained of pain during our interview, and at once produced his box of tablets. I begged him to refrain till I had examined his pulse, of which I took a tracing, and found extremely low tension—hyper-dicrotism. (See Fig. 8.)[2] I begged him most energetically to discard the nitro-glycerine, but, in my very presence, immediately after the prohibition, he swallowed two tablets consecutively. I have not seen that patient again. The case illustrates the importance of inculcating caution wherever a course of nitro-glycerine is prescribed. In cases manifesting high arterial tension without implication of the aortic valves, such doses—and it has been a matter of surprise that a dose of 1-200th of a grain three times a day suffices—may be continued for an indefinite time with nothing save advantage. It seems quite probable that the general arterial tension being thus relieved, atheromatous changes may be kept in abeyance. It is different, however, if disease exist about the aortic orifice; then the relaxation of tension may lead to an insufficient supply of blood through the coronary arteries to the heart. This is no valid objection to the *occasional* use of these medicaments in such a case, for heretofore I have found no treatment of greater value when pain is paroxysmal and severe.

Concurrently with these agents which immediately affect the heart and circulation, and occasionally for periods to supplant them, in cases in which the aortic valves are involved in atheromatous change, I consider that alkalies are of signal advantage. A very convenient form for protracted administration is this: of bicarbonate of potash and soda, of each ten grains; of powdered ginger, five grains; of powdered leaves of digitalis, one grain: the powder to be taken in water thrice daily one or two hours after meals. The iodides, especially the sodium iodide, have been strongly recommended in these cases, and, indeed, my friend and

[2] This tracing was taken previously to the interview here recorded. The tension was still lower on the occasion referred to.

Digitized by Google

colleague, M. Huchard, considers that iodide of sodium is almost a specific for angina.[3] In those in whom there is a distinct history of syphilis, the administration of the sodium iodide in gradually increasing doses, five, ten, fifteen, and twenty grains, three times a day, concurrently with cardiac tonics, is indicated, and I consider that M. Huchard's estimate of the value of the drug may be justified; but in others in whom the on-come of the disease has been gradual, and in association with lithæmia or with chronic renal disease, there is no advantage over the treatment by the alkaline bicarbonates, and in some the iodide is distinctly hurtful. Certainly I have not found it so uniformly beneficial as in cases of aneurysm of the thoracic aorta.

Concurrently with these means of internal medication and friction, massage, and in some cases systematic bathing, can, I consider, be proved to be of signal advantage. Liniment of aconite and belladonna may be employed, and often distinctly relieves the pain referred to the sternum, but for protracted daily use no liniment has any advantage over massage practised with the soft portions of the thumb and palm, dusted occasionally with a little lycopodium or powdered Fuller's earth. In a case of *advanced* atheromatous disease at the aortic orifice, I should hesitate before advising thermal treatment at any of the well-known watering places; but in a lady manifesting aortic obstruction, with albuminuria, which happily passed away, together with arthritis, I found great improvement follow a course of treatment at Aix-les-Bains.

As regards (3) the therapeutics of traumatic lesions at the aortic orifice, I shall only consider the evidence which cases afford in reference to the questions of (*a*) muscular exercise and effort, and (*b*) emotion. It has seemed to me probable that in times past the policy of rest may have been too rigorously enforced. A lesion of the aortic valves of whatever kind, if only regurgitation were in evidence, being diagnosed, the danger of movement was inculcated, and probably the fears of the patient unnecessarily invoked. A great protraction of rest in the recumbent or partially recumbent position may give too much repose to the heart, and, its physiological activity being suppressed, it is ready to follow the universal law of degeneration from disuse. On the other hand, the teaching of Oertel in favour of exercise pushed to the point of distress, and especially mountain climbing, in some forms of cardiac disease, may possibly induce evil in the opposite direction.[4] It can, I think, be taken as proved that even a healthy aortic cusp can be lacerated by physical effort, and that such may not be realised as a *violent* effort at the time of its production.[5] That the damage of an already diseased orifice can be increased by an undue effort is a proposition established *a fortiori*. Yet when an aortic lesion is quiescent and compensated, we have abundant experience to show that considerable exertion can be undertaken with the maintenance of seemingly perfect health. One of my patients was an energetic cricketer. To greatly reduce the amount of physical exertion in some cases would be to impart the danger of a lessened cardiac nutrition. The middle course is the best. First let us be assured that actual disease at the aortic orifice is quiescent, not progressive. Then commence with gentle exercise, always deprecating sudden effort. Every day the dose of exercise may be a little increased until our patient may be enabled to undertake such an amount as can ordinarily be sustained by an individual of his age, only under no circumstances should he be subject to *sudden* strain.

Now as to the effect of emotion in disease of the aortic valves, an effect that I think we are in danger of underrating. It may be a novel proposition that valvular disease may be *produced* by emotion, but I believe it to be true. I have been led to this view by the observation of a large number of cases of chorea. The most notable antecedents in cases of chorea in children are (*a*) rheumatism and (*b*) fright. In Dr. Stephen Mackenzie's most valuable Report on Chorea[6] it is stated that in 439 cases of the affection fright or shock was the immediate antecedent in 115, and rheumatism, acute or subacute, in 116 cases. It has been my experience, as probably it has been the experience of many other observers, to meet with cases in which a child, to all evidence perfectly healthy, has been the subject of a sudden terror and soon after has manifested the ordinary symptoms of chorea, and in such a valvular murmur has become audible. In some cases this murmur has been discovered with difficulty; a case has been examined again and again, and afterwards, on a given occasion, an apical or basic bruit has been noticed, which has in some cases become permanent, and in others has passed away. I have found a diastolic aortic murmur to have been thus manifested. As to the disappearance of such a murmur in course of time I am quite certain, for I have known one of the most musical character to become quite inaudible, and that without any sign whatever of infarction. When one considers the phenomena attendant upon sudden terror and the delicate structure of the cardiac valvular apparatus in childhood, I think we can arrive at a reasonable explanation. At the moment of fright the heart is inhibited, the arterioles contract, the surface is blanched, and the lips perhaps become livid from injection of the venous radicles. Then follows reaction, the heart palpitates violently, and the mitral curtains and aortic cusps may reasonably be expected to suffer from the violence. Pathological anatomy demonstrates to us that it is precisely at the margin of the valves where impact and attrition can occur that vegetations form. On this occasion I do not intend to develop this hypothesis further, nor do I wish it to be implied that I accept the embolic theory as explaining the universal causation of chorea, but I put it forward as a *primâ facie* case that in the delicate endocardium of a child it is highly probable that the vegetations of a simply papular endocarditis may be initiated by the palpitation due to sudden emotion. These considerations point to the importance of keeping a patient who is suffering from aortic disease, at any rate at periods when the endocardium may be considered unusually vulnerable, from mental as well as from physical shock. I may briefly here call attention to the question of the administration of hypnotics in aortic disease. When the heart is very irritable and palpitation is frequent, a wakeful night may mean much mischief. As a hypnotic, the action of which is attended with no ill consequence whatever, I have employed urethane in a single dose of twenty grains at bedtime; but this loses its good effect by frequent repetition. Paraldehyde, in thirty-minim doses in almond mixture, may be given as an alternative, the dose being repeated in half an hour if sleep fails to come. These failing, as they do when pain and distress are severe, then the hypodermic injection of morphia and atropine is the best course, and a few nights of such treatment may suffice to tide over the peril of insomnia. That insomnia is a peril in an aortic case I am well assured, though I am equally assured that the physician must take pains that the morphia habit be not inculcated.

I must now briefly consider the treatment in Class 4—septic or ulcerative endocarditis attacking the aortic cusps. In most cases—for in the majority the attention of the physician is not called till the destructive agencies have been too long in operation—it may be that all treatment is futile, but recent experience has convinced me that in all it is not so. I have recorded a case[7] in which I administered sulpho-carbolate of sodium in thirty-grain doses three times a day for thirty days with inunction of carbolised oil, and, apparently in causal relation with this treatment, there was an extraordinary recovery, so that the patient left the hospital in perfect health, with the exception that a slight diastolic murmur was manifest at the base. Since my paper was written I have had an opportunity of following the case to its end. The patient was readmitted nine months after her discharge with a renewed attack of the disease, which proved rapidly fatal. At the necropsy we found, besides innumerable recent vegetations, a small portion of one of the aortic cusps eroded as from an old disease. Micrococci were abundant, penetrating amongst all the recent exudation, but not into the deeper layer of old inflammatory tissue. The appearances gave one the notion that the old attack had been cut short, and so the evidence of morbid anatomy seemed to confirm that of clinical observation. It is evident that for the antiseptic agent to do its work efficiently there must be a certain time given, but that the blood can be charged with an efficient amount of substance capable of acting as a poison to micro-organisms seems in the highest degree probable. In any case manifesting the signs

of endocarditis, accompanied by very low arterial tension and not in definite association with rheumatism, I should advise the pretracted administration of the alkaline sulphocarbolate in large doses.

HYPERTROPHY OF THE LINGUAL TONSIL; USE OF GALVANO-CAUTERY; RECOVERY.

BY WILLIAM ROBERTSON, M.D.,
SURGEON TO THE THROAT AND EAR HOSPITAL, NEWCASTLE-ON-TYNE.

THE following case is judged worthy of reporting, both from the rarity of the affection and on account of its well-marked development. For the following notes I am indebted to Mr. P. R. Adkins, clinical assistant.

Mrs. G——, aged thirty-two (but looking ten years older), married, appeared for treatment at the hospital on Oct. 14th with the history of great distress in swallowing, readily produced difficulty in breathing, and inability long to sustain speech. The duration of these symptoms is now two years. The greatest caution has to be observed on swallowing, and she has not tasted beef for six months from fear of choking, The patient states that she has become much thinner during these two years, and has lost her colour and strength. She has, during the time stated, been forced to spend a considerable time over her meals. She complains, besides, of a feeling of foreign body in the throat, frequent swallowing, and pain shooting up to the left ear. The patient lives on a farm where the drinking water is not above suspicion, and is particularly disagreeable in summer time. A medium-sized œsophageal tube was passed readily, and withdrawn slightly tinged with blood. On examining the throat, extensive appearances of granular pharyngitis were found to exist on the oro-pharynx, and a slightly similar state was found in the naso-pharynx. On depressing the tongue, large pale œdematous granulations were brought into view, extending back over the dorsum linguæ. With the laryngoscope these were found continued back, gradually increasing in size on each side of the middle line to the epiglottis. In the neighbourhood of the epiglottis they were seen to rise to the level of its upper margin, and at the sides completely to overlap this organ, so that only a central part of it was visible. No interval or sulcus was thus seen between the epiglottis and the tongue. An effort to lift the epiglottis out of its bed in these masses effected no great separation, so close up to the epiglottis had the adenoid growths reached. These adenoid growths, as examined with the laryngoscope, were seen to be thickly set, of a pale œdematous appearance, and showed traces of blood on their surface caused by the passage of the bougie previously. Taken separately, each growth presented a bulbous extremity, three-sixteenths of an inch in diameter, with a narrowing base, and probably (some of them) six-sixteenths of an inch in length. Those in front and towards the margins of the tongue were flatter and smaller, but of the same appearance. As the patient came from a considerable distance, and the symptoms were urgent, the immediate use of the galvano-cautery was indicated. With the aid of the mirror the cautery was carried down as near as possible to the epiglottis, so as not to touch it, and the most prominent granulations destroyed, cocaine being previously used (which did not, however, ameliorate the symptoms one whit). Next day the patient expressed herself as easier, and stated that she had managed to swallow a piece of beef, a thing she had not done for six months previously. A subsequent examination showed that the cautery had been used effectually. The larynx was normal and readily surveyed, owing to the fixture of the epiglottis by the masses of the granulations.

Remarks.—According to McBride, who has given an extensive account of this affection in the September number of the *Edinburgh Medical Journal*, it would seem that cases of hypertrophy of the lingual tonsil have hitherto been very infrequently mentioned in British literature on the subject. The description here referred to leaves little for me to add. There are, however, one or two points in this case worthy of notice. The extreme difficulty in swallowing complained of led to the supposition that some obstruction existed in the œsophagus, which the passage of a bougie showed was not the case. The report shows that dysphagia was the symptom that brought the patient for treatment, and had materially affected her health and strength through interfering with due nutrition. The frequent passage of small particles of food "the wrong way" had often caused choking, and had gradually induced a dread in the patient to sit down to a meal, which was guardedly and slowly effected. The other symptoms—viz., fatigue on speaking, frequent swallowing, &c.—were well marked. The association of chronic inflammation of the adenoid tissue of other parts of the pharynx, which probably existed before implication of the same tissue in the tongue, is also suggestive, if we are to suppose that generally this process is an infective one, spreading from part to part after one locality in this region becomes affected. In this connexion it is to be observed that the drinking water used by the patient was probably polluted in some way. The unhealthy appearance of the patient also corresponded with that so frequently associated with granular pharyngitis, which I believe arises frequently (if not always) under insanitary conditions of one kind or another. As regards treatment, I know of no remedy short of galvano-cautery capable of meeting the necessities of the case. Its application is easily effected with the use of the mirror, and its action is local and precise. The pain, considerably assuaged by the previous use of cocaine, is trifling, and ends with its application, and little collateral œdema need be anticipated. The same cannot be said for chromic acid, which will spread, let it be ever so carefully used.

CASE OF PREGNANCY IN A RETROVERTED UTERUS,

WITH DISTENSION OF BLADDER AND SLOUGHING OF THE VESICAL MUCOUS MEMBRANE; RECOVERY.

BY J. G. G. CORKHILL, M.B. VICT., M.R.C.S., &c.

I HAVE to acknowledge my indebtedness to Dr. Barr, under whose care the patient was for kindly allowing me to publish this case. Although by no means unique, it is of sufficient rarity to warrant a notice by those members of the medical profession who in the performance of their daily task are liable to meet, and be compelled to cope with, the difficulties surrounding such cases. It does not in any way differ from other cases of its kind, the symptoms being straightforward and the signs unmistakable. Pregnancy, as is usual, appears to have taken place after the occurrence of the retroversion. A point in connexion with the after-treatment is that the uterus had to be washed out with an antiseptic lotion, owing to the retention of the secundines, which were not removed until the fourth day after delivery. Beyond a very slight febrile attack, lasting only about twenty-four hours, their retention appears to have been productive of no harm.

E. H——, aged twenty-eight years, married, applied as an out-door patient at the Stanley Hospital on Aug. 9th, 1886, complaining of very great difficulty in passing urine, which only came in drops, although the straining was very violent; and that her abdomen was also greatly swollen. Twelve months ago, whilst lifting a tub of water, she felt something give way in her right side, and in consequence had since not been able to lift heavy weights. Menstruation began at sixteen years; always quite regular except during pregnancy. Periods last five days; has never passed any clots, nor has she had any floodings. Has had five children, last eighteen months ago. Menstruation began three months after the last confinement, and continued regular until April, 1886. About the middle of July, during micturition, she was seized with very severe bearing-down pains, accompanied with cutting pain in the genitals and cessation of micturition. Since then micturition has always been very painful and scanty, and effected only by the most intense straining. Towards the end of July the abdomen began to enlarge, which it has continued to do until it reached its present size. Bowels are habitually constipated.

Condition on admission.—She is very anæmic and waxy-looking, and wears an expression of great anxiety. Well nourished. Areolæ of nipples somewhat pigmented, though not markedly so. In the lower part of the abdomen, but extending through the umbilical into the epigastric region, and invading laterally the lumbar regions, is a round, uniformly globular tumour, elastic, though fluctuation cannot be made out. Percussion note over tumour is absolutely dull, whilst the flanks are resonant. The top of the tumour reaches five inches and a half above the umbilicus

Digitized by Google

abdomen at the level of the umbilicus measures forty-one inches. Per vaginum, the os cannot be felt with the finger. The whole of the Douglas pouch is blocked by a soft, globular, uniform tumour, which, pressing backwards, fills up the whole of the sacral curve. With the hand in the vagina, the os can just be felt above the pelvic brim. In front the pelvis is quite blocked by a soft, very elastic tumour. The vulva has a very congested appearance. Bowels very constipated.

An attempt was made to pass a catheter, which was unsuccessful, nor was this accomplished until after an anæsthetic had been administered on Aug. 10th., when six pints of very fetid urine were very slowly drained away.

Until Aug. 17th she appeared to be doing well, when she complained of aching pain in the lower part of the back, and in a few hours had a flooding. She was kept very quiet, and had some liquor opii sedativus; but on the 18th she had a miscarriage, the after-birth being retained. The uterus was washed out with a solution of carbolic acid (1 in 100) and tincture of iodine (one drachm to the pint).

She continued well until the 21st, when she had a rigor, the temperature rising to 103·2°, and the pulse to 132.

On Aug. 22nd the secundines were removed, and the temperature fell to normal, and the pulse to 108. Since admission the bladder has been washed out night and morning with a solution of quinine (two grains to the ounce).

Sept. 7th.—Has been fairly comfortable since last note, though the vulva has been very much swollen and exceedingly tender; catheterism has produced intense discomfort for some time, though she always feels much relieved when she settles down again. For the past week or ten days she has had incontinence of urine, not being able to hold it at all. The syphon had to be given up, and a double-eyed gum-elastic catheter substituted, as the lotion would only pass in, but not return. Since Sept. 1st a very thick, tenacious, foul-smelling discharge has followed the washings; so that on the 4th the quinine lotion was changed to one of boro-glyceride. Yesterday, protruding through the meatus urinarius, was a whitish-grey, tough, and sloughy-looking substance, on which slight traction was made, and as much withdrawn as possible, when it was cut off and the stump returned.

10th.—Night and morning since last note the same slough substance presented itself, and was treated in the same manner.

26th.—Now almost quite well; has no pain; can hold urine indefinitely; can wait about ten minutes after desire to pass it comes on.

Oct. 9th.—Up to-day. Feels weak. Urine still well retained. Slight deposit of muco-pus.

Nov. 3rd.—Feels very well. Urine still retained well; there is no deposit. Discharged cured.

Matlock.

SUPRA-PUBIC CYSTOTOMY.

BY ROBERT CRAN M.D., M.C.,
CIVIL MEDICAL OFFICER.

THE following case will probably be of sufficient interest to warrant its publication in THE LANCET.

B——, aged about thirty-five, a native of Chota Nagpore, and a new arrival in this province, was brought to my notice on April 12th last, with the following history and symptoms. As a child he had suffered every two or three months from difficult and painful micturition. As he grew older the symptoms became more pronounced and the intervals between the attacks of shorter duration, and for the last seven years he has suffered great and almost constant pain, with extreme difficulty of micturition and profuse hæmaturia. Occasionally small particles of stone were passed, and once, on taking some native medicine, a considerable quantity of grit came away. The patient is married, and has three children, all well; he is a big, powerful man, and fairly well nourished. On examination I found him passing blood in considerable quantities, and in great pain. The sound at once came in contact with a large calculus, lying across the mouth of the bladder, which I could neither move with the sound nor with my finger in the rectum, and calculated it to be about the size of a small goose's egg. Considering it too large either for lateral lithotomy or lithotrity, I decided, after consultation with M. Cantin, to perform the supra-pubic operation.

On April 24th the patient was put under the influence of chloroform, and as much carbolised water injected into the bladder as possible. A catheter was then passed and the point of it made to press against the anterior wall of the abdomen, to serve as a guide. I then made an incision about three inches long, commencing from the symphysis pubis, and in the middle line, and dissected down to the veins overlying the bladder, which I carefully separated with the handle of the knife before wounding the viscus. The stone was then seized with the forceps, but it was too large to be extracted, and the incision had to be enlarged before its removal. Small particles were broken off by the forceps. These were washed out, and the wound sewn up and dressed with carbolic dressing. A gum-elastic catheter was passed, and a dose of opium administered. Throughout the operation the peritoneum was not seen. The stone was composed of phosphate of lime, was kidney-shaped, weighed five ounces, and measured 3⅛ in. by 1¾ in. In the afternoon the patient complained of much pain, and had more opium given him.

April 25th: Morning temperature 99·8°; pulse 116. Pain somewhat less. Slept fairly well. Ordered a mixture of tincture of opium and dilute nitric acid three times a day; and to have milk, chicken soup, sago, and barley-water. Evening temperature 99·1°; pulse 108. Skin hot and dry. Passed about two ounces of urine by catheter.—26th: Temperature 99·6°; pulse quick. Slight tympanites. Tongue dry; skin hot. Ordered a warm water and castor oil enema, which moved his bowels and relieved the tympanites. Evening temperature 99·7°. Had a second stool. Tympanites less.—27th: Temperature 100°. Tympanites almost gone. Ordered another enema.—29th: Removed dressing; urine was discharged by wound, which was looking healthy and partly united. Patient well on the whole. Put in a fresh catheter, and dressed the wound with carbolic acid dressing. Appetite good. Continued the acid and opium mixture, also his milk, soup, sago, and barley-water. From this date the patient had an uninterrupted recovery. The urine was passed almost entirely by the wound for about three weeks. As the wound closed, the urine was gradually passed by the natural passage until May 28th, when the wound was closed. On June 3rd the wound was healed over, and the patient discharged on June 6th perfectly well.

Remarks.—I do not know that there is anything very worthy of remark in the above case, unless it be the persistent discharge of urine from the wound, which undoubtedly retarded the healing process. It is the first time I have had occasion to perform supra-pubic cystotomy, and I do not think it is such a satisfactory operation as lateral lithotomy where that operation can be performed. The wound is much longer in healing; the urine flowing from the wound keeps the patient continually wet and in a very miserable, filthy condition. The above case was in hospital forty-two days, whereas the longest time I have had a case of lateral lithotomy in hospital was twenty-three days, and the shortest nine days. I have operated on a good many children, and never found much difficulty in extracting the calculus with a nasal polypus forceps.

GUY'S HOSPITAL.

EPITHELIOMA OF THE LIP AND GLANDS [illegible] AFTER REMOVAL; EXCISION OF THE [illegible] TWO INCHES OF THE INTERNAL JUGULAR [illegible] POSURE OF THE DEEP VESSELS AND [illegible] GASTRIC SYMPTOMS; RECOVERY.

(Under the care of Mr. R. C[illegible])

We have recently given [illegible] epithelioma of the [illegible] growth [illegible] specimens of [illegible] [illegible] [illegible]

Digitized by Google

was much less extensive, but involved the internal jugular vein (which was thrombosed above and below the invading growth), and the removal of the growth necessitated manipulation and separation of the pneumogastric nerve, which had been partly surrounded. The account of the symptoms which followed the operation and Mr. Lucas's remarks on the case will be read with much interest. We are indebted for the notes to Mr. Grosvenor.

The patient, a strongly built man, aged forty-seven, by trade an engine driver, was sent to see Mr. Lucas by Dr. Andrews on Oct. 13th, 1887, and he was admitted into Job ward on Oct. 17th. He stated that his parents lived to old age, that he was married, and had always enjoyed good health. He had never smoked or chewed tobacco. Six years ago he took a severe cold, and a sore then appeared on his lower lip, which refused to heal. Three years later he was struck on the lip by a lever of his engine, and received the blow, which knocked out a lower incisor, just on the sore. This made the lip more painful, and the superficial layer of skin and mucous membrane peeled off. About two years ago the lip became painful, and he found the sore extending. He then consulted a doctor, and the sore was burned with nitric acid. Caustic treatment was continued for fifteen months, but the glands becoming enlarged he was advised to apply to a metropolitan hospital for relief. This he did in June last, and underwent an operation for the removal of a portion of the lip and the submaxillary glands, which were enlarged, on both sides of the neck. He made a good recovery, but never was quite free from pain in the lip, and at times this was excessive, so he returned again in August, and had a V-shaped portion removed from his lower lip. He then went into the country, but whilst there he noticed the glands under the right sterno-mastoid muscle enlarging. Consequently he applied again at the same hospital, and was put under chloroform, but no operation was performed, as the disease was considered to be too extensive. This he only communicated after the operation, lest it should deter Mr. Lucas from operating, and he came determined to undergo it at all hazards.

State on admission.—He was suffering great pain, extending from the angle of the jaw to the clavicle, and shooting up on the side of his head. The lower lip was occasionally very painful, the inner side being inflamed, swollen, and tender to the touch. On the right side, extending from just above the angle of the jaw to an inch and a half below, and from under the sterno-mastoid to an inch in front of the angle of the jaw, was a large mass of glands hard to the touch, and not movable on subjacent parts.

Operation.—The pneumogastric nerve was dissected out for more than two inches, but the sympathetic nerve was not seen. At this stage of the operation the patient's breathing became very shallow, and his pulse feeble and slow. Ether was at this point substituted for the chloroform. The growth was then dissected up, and its superior posterior relations divided, the superior thyroid and lingual arteries being distinctly seen arising from the external carotid artery. The spinal accessory nerve was also dissected out, and seen to enter the sterno-mastoid muscle. The wound was then well sponged with carbolic acid lotion (1 in 40) and the edges brought together with wire sutures, a large drainage-tube, directed upward, being inserted where the incisions impinged upon each other. The wound was dressed with oiled silk protective and carbolic gauze strips sprinkled with iodoform, and a gauze bandage applied. Carbolic spray was not used, but during the operation the wound was saturated with carbolic acid lotion (1 in 40).

At 5.30 P.M. the patient was carried back to the ward and put to bed. He then had an attack of syncope, from which he was aroused by friction, during which the pulse was 44 and the respiration very shallow. Amyl nitrite inhalations were applied over the patient's mouth and nose and hot sponges to the chest, and subcutaneous injections of brandy were given. He then had an attack of vomiting, and appeared for a few minutes relieved. At 6.30 P.M. the patient's pulse was 44 beats per minute, and he was still lying in an unconscious state. At 7 P.M. the pulse quickened to 56, and he showed signs of regaining consciousness. An enema of an ounce of brandy was given, and afterwards enemata of milk and beef-tea were injected. At 11 P.M. the temperature was 99·6°, pulse 74, respiration 24, and all anxiety as to his condition was over. At 12 P.M. the temperature was 100·3°, pulse 72, respiration 22. The patient now had a sound sleep and perspired freely. At 1 A.M. the temperature was 100·4°, respiration 24, and pulse 74 (more irregular). The patient slept well, awaking about every hour. He then turned upon his side, and dosed again immediately.

Oct. 23rd.—The patient felt fairly comfortable; he had a good pulse. An attack of vomiting seized him in the morning. There was not much discharge from the wound, and it looked healthy.

24th.—The drainage-tube was withdrawn; the wound looked healthy, and there was but very slight discharge. He was put upon a liberal milk diet, with the addition of four ounces of brandy daily. The enemata were omitted.

25th.—The wound was dressed again, and an egg-and-milk diet ordered.

28th.—Five stitches were withdrawn, and patient was put upon middle diet.

30th.—The remaining stitches were removed, and a full diet ordered.

31st.—The patient left his bed for a short time during the evening.

Nov. 4th.—The wound is doing well. The incision over the anterior margin of the sterno-mastoid has quite healed, and the one under the jaw is showing signs of rapidly uniting. The patient feels uncomfortable about the condition of his lower lip, and wishes to undergo an operation "to entirely cure him."

8th.—Cocaine was injected hypodermically and also painted on the external surface of the lower lip over the old cicatrix. Mr. Lucas then made two convergent incisions, about half an inch apart, at the margin of the lip, extending to the angle of the chin, through the whole thickness of the lower lip; thus, a triangular piece of the lip was excised, including the old cicatrix; the two portions of the lip were brought together by means of two hare-lip pins, bound round with thread; four wire sutures were then inserted and the mucous membrane united by silk sutures; gauze dressing was then put over these and enclosed in a bandage.

9th.—Wound dressed, and appears to be uniting by first intention.

11th.—The pins were withdrawn and the stitches removed. The next day he left the hospital.

Description of the growth removed.—The mass removed measured an inch and a half by an inch, the long axis being vertical. It consisted partly of the carotid glands and partly of the sheath of the carotid artery, with about an inch and a half of the internal jugular vein. There were three glands, the highest being the size of a filbert, the lowest the size of a small bean. All three were hard to the touch, and on section showed hard whitish patches, which the microscope showed to be secondary deposits of an epitheliomatous nature. The glands were closely adherent to the sheath of the carotid, and this was adherent to the wall of the internal jugular vein over an area about the size of a threepenny-piece, situated about the middle of the anterior aspect of the part of the vein removed. On making a section of the vein at this point a white dense mass was seen to occupy the lumen of the vessel, which was here somewhat dilated. This mass was traceable through the vein wall directly to a small nodule situated on the carotid sheath. Microscopic examination showed these masses to be epithelioma infiltrating the wall of the vein and occluding its lumen. The rest of the vein was occupied by a partially decolourised clot, which contained no trace of growth.

Remarks.—So tedious and difficult an operation, involving the exposure of all the most important structures in the neck, and necessitating the removal of a considerable portion of the internal jugular vein, would not have been undertaken had not the patient been fully convinced that his only chance of relief was by operation, and firmly resolved to undergo anything that might lessen the pain from which he was suffering. So determined was he to submit to anything which might be prepared for his good that he kept back the fact from his surgeon how he had been under chloroform for an operation some weeks before, and it had been given up as too serious to be justifiable. The man's general health, however, was excellent, and his rapid recovery after the operation showed that no miscalculation of his recuperative powers had been made when it was resolved to attempt removal of the growth. The risks, then, depended on the immediate effects of the operation, and with these Mr. Lucas felt himself able to cope, even though the disease involved (as was proved) the main vessels and nerves of the neck. The dissection occupied two hours and a half, and it

Digitized by Google

found necessary to remove two inches of the internal jugular vein which the growth had invaded. When dissecting out the pneumogastric nerve the patient's condition became somewhat critical, and it was found advisable to substitute ether for chloroform till the end of the operation. After the patient had been removed to bed the effect of the irritation of the pneumogastric was evidenced by syncope and a pulse of only 44. Stimulants of various kinds were administered, and he gradually regained consciousness, but it was not until five hours later that it was considered safe to leave him. It is certain that the symptoms were the direct effect of the pneumogastric irritation, as he lost scarcely any blood, and no spray was used which might have added to the shock. The pathological specimen was interesting as showing the little resistance the coats of a vein offer to the inroads of cancer, compared to those of an artery when equally exposed. The growth had not only penetrated but filled the lumen of the vein at one point, whilst clotting had taken place above and below. The sheath of the carotid artery had to be taken off, but the proper coats of the vessel were uninjured. After the first twelve hours there was never any anxiety as to his recovery, which was complete in a fortnight. Before leaving he insisted on having the old painful cicatrix in his lip re-excised, and this was done under the influence of the subcutaneous injection of cocaine.

WEST HERTS INFIRMARY.

CASES OF SURGICAL INTEREST.

(Under the care of Mr. F. C. FISHER.)

THE following cases are a continuation of those of last week:—

CASE 3. *Gunshot wounds of shoulder and of face.*—A. N——, aged twenty-four, married, was admitted on March 26th, 1887. At 5.30 A.M. on the day of admission she was fired at by her husband; she was lying in bed, and he standing by her on her right side. On attempting to shoot her she grasped the barrel of the pistol with her right hand; he, however, fired, and the bullet ran up parallel with the arm and entered the lower and anterior margin of the deltoid muscle. She then let go, and turned her head away from him, when he again fired, and hit her just in front of the junction of the helix and tragus of the right ear. She did not lose her consciousness, and walked to the infirmary, which was about a mile distant. On examining the patient at 9 A.M., the right hand between the forefinger and thumb was blackened by powder, the right cheek was swollen and shiny, and she presented wounds one-eighth of an inch in diameter at the above-named sites. She was seven months pregnant.

Operation.—On examining the wound in the head, the probe travelled downwards, forwards, and inwards through the tissues of the temporal fossa, and struck on the tuberosity of the superior maxilla. From that point the bullet had evidently bounded into the cheek. On the inside of the mouth there was a small bruise, evidently caused by counter-pressure against a tooth. An incision was made over that spot, and the bullet was believed to have been struck, but the soft parts overlapped it, and it could not be removed. On examining the shoulder, the probe passed four inches and a half upwards, backwards, and outwards, and lodged in the head of the humerus, which was splintered. The sinus was slit up sufficiently to allow the finger to examine the parts. Several small loose fragments of bone were removed, and then the bullet was seized with forceps and extracted. It was firmly wedged in the bone, and required some little force to be used. A drainage tube was inserted, and the wound treated with the usual Listerian precautions.

During the operation labour pains set in, and she was delivered of twins the next morning. A good deal of fever followed; the temperature gradually rising to 104·4° F. on the sixth day. Uterine discharges natural, no abdominal pain. Cheek much swollen and fluctuating. An abscess was opened externally on the cheek, but the bullet could not be struck by the probe. Shoulder wound healthy. The temperature rapidly fell after this, being 99° on the eighth day. From this point she went on steadily improving. On April 29th, thirty-three days after the occurrence, the bullet, now being plainly felt, was cut down on and levered out of the wound. The wound rapidly healed. On June 9th the patient was discharged, with the sinus in the shoulder not quite healed. One month afterwards she returned, the shoulder being quite sound and with good movement.

Remarks by Mr. FISHER.—I am inclined to think that the fever she had was the result of the abscess in the cheek. It certainly was perplexing to know how to deal with a woman in the parturient state and with two bad bullet wounds, accompanied by a temperature of 104·4°. The way in which the loose tissues of the cheek kept rolling over the bullet was most annoying. It seemed impossible to fix it, especially as I did not want to leave a large scar on the cheek. The resulting scar is not more than half an inch in length, and is not puckered. The bullets demonstrate by their markings the course they travelled: the one with a deep cut in one side, but otherwise fairly preserving its shape, being the one from the humerus where the hard cancellous tissue cut the bullet like a chisel; the other, with a long, smooth side, caused, I take it, by gliding past the inner surface of the zygoma or else the temporal fossa.

CASE 4. *Genu valgum on both sides; osteotomy on the left side; cure.*—G. O——, aged nineteen, was admitted on March 31st, 1887. Three years ago he was an in-patient at the infirmary for genu valgum, but declined treatment. The legs becoming worse, he reapplied to have them operated on. On admission, he presented a condition of well-marked genu valgum, the inside measurement between the heels being ten inches. The deformity was greater on the left side. On April 15th, after consultation, it was decided to operate on the left femur by Macewen's method; this was done under antiseptic precautions, and the limb brought straight. The case ran an aseptic course, finally leaving an elongated ulcer at the site of incision. This was healed by May 16th, when the limb was put up in plaster-of-Paris. He was discharged, walking with the help of a stick, on May 26th. He returned in six weeks' time, and had the plaster removed. The joint required a little passive motion, and then all the ordinary movements returned.

Medical Societies.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

Trephining in Brain Disease.—Serious Brain Symptoms following Pyæmia.

THE opening meeting of the Surgical Section of the Academy was held on Nov. 11th, A. H. Corley, M.D., President, in the chair.

The PRESIDENT delivered an inaugural address outlining the history of surgery for the past fifty years.

Mr. J. DALLAS PRATT read a paper on a case of Mastoid Disease with Discharge of Pus from the Middle Ear, in which he had successfully trephined, the trephine being applied on the spot indicated by Mr. Wheeler, so that the crown of the instrument was anterior to a line bisecting the mastoid vertically and the lower border of the crown, on a level with the external auditory meatus. The membrana tympani was perforated, and there were pain and tenderness in the mastoid region, with deafness. After the operation, which opened the mastoid cells, the middle ear, and the cranial cavity, the patient's temperature only rose above normal on one evening. The pulse never exceeded 80. The patient made a good recovery. The discharge from the ear ceased, and the membrana healed up; the deafness also disappeared. Mr. Pratt drew attention to the statistics, thirteen cases having been operated on in this manner with only two deaths, or 84 per cent. of recoveries; whereas the operation of gouging, drilling, or opening the mastoid cells by means of a bit produces a mortality of about 27 per cent. He advocated the use of the trephine, even if the mastoid cells alone were to be opened, as being more manageable and safer than the other instruments, and drew attention to the fact that of eight cases in which no operation was done, there had not been a single case which recovered. He advocated the performance of this operation in cases of prolonged otorrhœa, where milder measures had failed, even when no bone disease was present.

Mr. MAYNE (Longford) read a paper on Serious Brain Symptoms following Pyæmia. A. B——, aged twenty-seven, who had a slight scratch on her finger, had been dressing a wound. A few days afterwards the finger got sore; the

Digitized by Google

glands in the axilla also became enlarged and inflamed. These symptoms passed off, but after some days the throat got sore and an abscess formed in the tonsil, which was opened, when a quantity of pus escaped. Soon after this the parotid gland inflamed, suppurated, and burst into the external ear, through which pus freely escaped. After sitting at an open window in a draught, paralysis of the left side of the face set in, which was cured by counter-irritation and galvanism. She complained, after some days, of severe pain in the right side of the head, and was very irritable. Anodynes were given, which had very little effect in relieving the pain or procuring sleep. The vision of the right eye became impaired; she complained of tears flowing into the right eye, preventing her seeing, and the pupil was contracted. After a drive in a very easy carriage, she became more irritable, and could not sleep. She had a severe rigor, and declared she could not bear the pain of the right side of her head. There was paralysis of the right side of the face, tingling of the left arm, she dragged the left leg, the right pupil was dilated, and she misapplied words. For some days the symptoms became more marked. Mr. Fitzgibbon trephined the left mastoid, but on removal of bone there was no sign of pus. For several days all the symptoms appeared aggravated, the paralysis being well marked, and the sphincters also paralysed. After some days the paralysis passed away, but was succeeded by noisy delirium, which continued for several weeks. Counter-irritants were applied to the head. Tonics, iodide of potassium, and iron, with cod-liver oil, were given internally. Eventually health was restored, and the mind became normal. Mr. Mayne was unfavourable to the trephining of the mastoid, although the patient had had in early life otorrhœa after scarlatina, but the discharge had not been present for years, and as during that time she had not been troubled with any brain symptoms, he saw no grounds for believing that trephining the left mastoid would benefit the case. All the symptoms pointed to brain trouble on the right side, probably about the fissure of Rolando. Had there been any evidence of mastoid trouble, such as Mr. Wheeler records on p. 61, vol. i., of the Academy's Transactions, he would not have been so opposed to the operation.—Mr. HENRY FITZGIBBON regretted the want of notice of Mr. Mayne's paper, as he would have liked to consult his notes of the case, it being the subject of a paper which he himself read before the Academy last session; but speaking from memory as to the condition of the patient at the time of the operation, he was satisfied the disease had originated from inflammatory action extending from the left mastoid region. It seemed to him that the lady had had otorrhœa more recently than Mr. Mayne mentioned. At any rate, her state appeared to Mr. Wheeler and himself to be perfectly hopeless, except, as the only chance of recovery, by giving relief to some pent-up intracranial matter. While admitting that trephining the mastoid process was not unequivocally indicated, all he proposed to do was to trephine where he thought trephining would give relief.—Mr. BENNETT submitted that diagnosis should be carried forward to a greater degree of certainty than was at present attained before adopting Mr. Pratt's rule, that the trephine should be applied in almost all cases of otorrhœa where the discharge was maintained a considerable time and did not yield to other means. He had investigated two or three cases in which the path of fatal inflammation proved to be along the auditory nerve to the base of the brain.—Mr. THOMSON said Mr. Mayne's case raised some interesting points, as being one of pyæmia. The lady, from Mr. Mayne's version, seemed to be suffering from left hemiplegia, and the trephining took place on the left mastoid process, or in that region. He wished to know from Mr. Wheeler, who consented to the operation, why, having regard to the localisation of functions, that particular position was selected; and whether he considered that the removal of a piece of bone from the left mastoid region was calculated to improve hemiplegia occurring on the same side. It appeared from Mr. Henry Fitzgibbon's statement that no pus appeared until the fourth day, when it was manifest. There was nothing remarkable in that. If a piece of bone was removed and the case allowed to go on for four days, unless the wound was strictly aseptic, it was not an unlikely condition that there should be pus. The symptoms produced by pressure were explained by the pus pent up in the wound for a certain time.—Mr. WHEELER, like Dr. Fitzgibbon, regretted he had no notice of Mr. Mayne's paper, which was similar to a case operated on sixteen months ago by Dr. Fitzgibbon, who had communicated the details already to the Academy. It was difficult after so long an interval to recall in a moment the particular condition of the case. He concurred in the remark that trephining should not be used indiscriminately for the cure of otorrhœa. There were cases which could be satisfactorily treated by other means. But, in cases of prolonged discharge pressing through an opening in the membrane, the operation was indicated; as also in cases associated with bone disease, and where cerebral symptoms supervene from continued or suppressed discharge.—Mr. FRANKS said the impression left by Mr. Henry Fitzgibbon's paper was, that Mr. Mayne's case was probably a pyæmic one, and there was no reason why the patient should be trephined on the left any more than on the right. He entered a protest against wholesale trephining of the mastoid process. Dr. Myles had called attention to a skull upon which he showed that Mr. Wheeler's method would open the lateral sinus. He, too, had another skull himself, which would show that operating in the same place the trephine would go into the middle of the lateral sinus.—Mr. PRATT, in reply, said he would undertake to trephine by Mr. Wheeler's method the skulls referred to by Dr. Myles and Dr. Franks, without going into the lateral sinus at all. It should be remembered that the lateral sinus was not opened in any of the cases in which that method was adopted. The treatment was iodoform and boracic acid; injections of perchloride of mercury and boracic acid. He disagreed as to the desirability of waiting for intracranial symptoms, believing that by so waiting nine-tenths of the cases would die. No insurance company would grant a policy where there was otorrhœa, and hence the disease was looked upon as more serious than Dr. Franks thought. He did not regard abscess of the ear as a rare complication.—Mr. MAYNE also replied.

MIDLAND MEDICAL SOCIETY.

A MEETING of the above Society was held on Dec. 7th, Mr. Ross Jordan, President, in the chair.

Compound Fracture of the Femur.—Mr. A. F. MESSITER showed a boy aged fifteen, who was admitted to the Queen's Hospital on March 31st, under the care of Mr. Bennett May, with a bad compound fracture of the femur. The lower end of the upper fragment was protruding through a large wound on the outer side of the limb; the ends of both fragments were stripped of periosteum for about two inches. Under an anæsthetic the fracture was reduced, an extension apparatus applied, the trunk and limb firmly fixed on a Thomas's hip splint, and a free incision made through the muscles and skin at the back of the thigh to provide for drainage. At the end of fourteen weeks union was firm. Two sinuses led down to the necrosed bone, of which four fragments were removed at the end of five months from date of accident. After another two months all wounds had healed, and the patient was getting about with one inch of shortening.

Unilateral Facial Atrophy following Puerperal Eclampsia. Dr. BARWISE showed a woman, aged forty-three, who had been perfectly healthy until confined of her fourth child eighteen years ago. After the confinement she had convulsions, and her husband noticed that she was looking old; the hair on the right side came off in considerable quantity. She became subject to fits, which she continued to have for two years and eight months, when she was delivered of a son. This boy was an epileptic imbecile; no fits have occurred since his birth, but her face has continued to atrophy on the right side. Dr. Barwise considered that the cause of the lesion is probably pressure upon and destruction of part of the fifth nerve (as it passes from the pons along the base of the skull) by an effusion which took place during the puerperal convulsions.

Dr. SAUNDBY read a paper on Hæmaturia.

Epiphysitis of Femur.—Mr. BARLING showed a boy, aged six years, who had suffered from epiphysitis with acute inflammation of the knee joint. When admitted to hospital the knee was hot, swollen, and very painful, but there was only a small amount of fluid in the joint; the evening temperature was 102°. The limb was fixed on a McIntyre splint and the joint was kept cool, but the constitutional disturbance was severe, the temperature reaching as high as 104°. Ten days after admission some thickening was detected on the outer side of the femur immediately above the joint; two days later, the skin over this being red and œdematous, an incision was made. No pus was found, only

Digitized by Google

granulation tissue, evidently arising in connexion with the epiphysis. The inflammatory material was scraped away and the cavity drained. This was followed by decided improvement, both local and general, but nine days later the temperature had again risen. Examination detected thickening in the popliteal space. This was incised, and a condition similar to that on the outer side found, which was treated in the same manner. From this time the joint steadily progressed to recovery, and now, three months later, the patient is free from pain, is able to flex his knee to a right angle, and gets about on it as freely as he ever did.

Aphemia.—Dr. SUCKLING showed a case of aphemia. The patient, a girl aged nineteen, was suffering from paresis of the right side of the face and right hemiplegia with late rigidity, the deep reflexes with ankle clonus being well marked on the right side. No history of syphilis, rheumatism, Bright's disease, or of the specific fevers could be obtained. On Jan. 10th last she was suddenly attacked while sitting at work, losing consciousness, and being paralysed on the right side; the coma lasted about one hour. She had complained of headache for some days before the attack. She never spoke after the attack for a week, when she said the word "mother," and later on said "yes" and "no." After a considerable stay in the hospital she could say "sister," "yes, sir"; when told to repeat a word, she would say "sister," "mother," words that she had previously recovered, and which were mainly automatic. She understands what is said to her; she can read, also write with the left hand, there being no sensory disturbance and no agraphia. Dr. Suckling pointed out that the aphasia was probably both sensory and motor at the onset, the sensory disturbance having been recovered from, it being very unusual for a pure motor aphasia to accompany severe hemiplegia. Since the onset of the hemiplegia she has had several attacks of Jacksonian epilepsy on the paralysed side (pointing to cortical mischief). Dr. Suckling considered that the lesion was probably thrombosis of the left middle cerebral artery, the branch to Broca's convolution being occluded, softening of the internal capsule and third left frontal convolution having followed. The other cortical centres for speech probably recovered from the establishment of a collateral circulation, the patient's age favouring this supposition. There was no change in either fundus oculi, and no albuminuria or heart mischief.

Obstructed Bile Duct.—Dr. HOGBEN exhibited the liver removed from a woman eighty-nine years of age. The common bile duct was widely distended by a hard mass of inspissated bile. The gall bladder contained a little bile mixed with mucus. There was no bile in the duodenum, and no jaundice was observed.

NORTHUMBERLAND AND DURHAM MEDICAL SOCIETY.

A MEETING of this Society was held on Dec. 8th, Dr. G. H. Hume, President, in the chair.

Cicatrix on Arm of Girl.—In the absence of Dr. Heath the patient was exhibited by Dr. OLIVER, who drew attention to the fact that she was now brought for the third time before the Society to show the result of treatment. At various stages of the disease chloride of zinc paste and grafts of skin had been applied, and the result was a useful arm.

Excisions of Joints.—Dr. HUME exhibited two cases of excision of the knee; in both ivory pegs were employed, some of which, when removed, were found to be eroded. Dr. Hume also exhibited a boy whose ankle joint he had excised, also successfully, for deformity arising from injury.—Dr. ARTHUR CAMPBELL exhibited a girl whose knee joint he had excised twice. Though the operation had to be performed amidst most unhealthy surroundings, the patient made an excellent recovery.—Mr. RUTHERFORD MORISON exhibited a case showing the result of excision of the elbow joint, and another case showing the result after removal of two inches and a half of the lower end of the fibula. An extensive dissection had to be made in the latter case to allow of the removal by means of the chisel of a cartilaginous tumour. This has not returned; the patients walks quite well. In the former case movement was begun on the fourth day, and has been continued ever since.—In the discussion which followed, Dr. ARNISON alluded to some of his excisions of the knee, in one of which a movable joint had been obtained; and that whilst as a matter of fact the joint, though movable, had become stiffer of late, his opinion was that a stiff joint gave the best results.—Mr. CROFT (St. Thomas's Hospital) concurred with the previous speakers as to the advisability of the operation. He gave up some time ago the use of ivory pegs, having had excellent results from the employment of platinum wire sutures.

Traumatic Dislocation of both Lenses.—Dr. MURPHY exhibited a man from whose right eye he removed a lens dislocated by accident, and who a few months afterwards again presented himself with the lens of the other eye dislocated. This he did not remove; it is now undergoing absorption.—Mr. WILLIAMSON spoke in favour of removal of the lens in these cases.

Leucoplakia of Tongue.—Dr. MURPHY exhibited a man whose tongue presented well-marked characteristics of this disease. The patient had improved under treatment by arsenic and iodide of potassium internally. He thought that most of these cases became cancerous ultimately.—Dr. DRUMMOND regarded most of them as syphilitic.

Excision of Condyle of Lower Jaw in a Boy.—Mr. PAGE exhibited this patient. An account of the case has already appeared in the journals.

A Man whose Spinal Accessory Nerve was Stretched for Torticollis following Injury to Neck.—Mr. PAGE exhibited a patient. The result was in every way satisfactory.

Mitral Stenosis.—Dr. DRUMMOND exhibited a patient, a girl fifteen years of age. Over and internal to the apex beat could be heard a well-marked presystolic murmur. The murmur was loud, rough, and prolonged, began almost immediately after the second sound, and ran up and ended in a snap, which he regarded as the termination of the first sound of the heart. He could not accept the views which had lately been put forward in a revived form by Dr. Dickinson, that the murmur which was heard in this case was one of mitral regurgitation. To him, the murmur was heard so distinctly in the post-diastolic or presystolic period, that time could not have been given for the left ventricle to fill, much less for regurgitation to be taking place. The strong impulse felt over the apex area in many of those cases was no argument, to his mind, against the murmur being presystolic, as from the extended area of cardiac dulness noticed in many of these cases he was of opinion that the largest part of the pulsation was due to the action of a dilated and hypertrophied right ventricle.—Dr. OLIVER supported Dr. Drummond in regard to the case being one of mitral stenosis, and as to the murmur being presystolic; he considered the case to be one of pure and uncomplicated mitral stenosis; if regurgitation was present it was extremely slight. He agreed with Dr. Dickinson as to the existence of a diastolic murmur at times over the mitral area, and said that in many of his cases of heart disease, where aortic regurgitation was absent, he had frequently diagnosed mitral stenosis from the presence of a murmur there, diastolic in rhythm, and almost always associated with a systolic, and post-mortem examination had confirmed the diagnosis. But he still believed in the presystolic time of the murmur of mitral stenosis, and also pointed out that, from the murmur so closely following upon the second, time was not given for the murmur to be one of mitral regurgitation. The pathological changes found in the walls of the left auricle and right side of the heart were, in his opinion, capable of explaining the loudness of the murmur.—Dr. FINLAY (Middlesex Hospital) thought the question was only to be settled by appealing to facts. On examination the long rough murmur ceases as the systole of the ventricle is felt by the finger on the carotid artery. If the murmur therefore ceases with the beginning of the ventricular systole, he did not see how the murmur could be anything but presystolic. The point of greatest intensity of the murmur was also a matter of importance, the murmur of mitral regurgitation is heard at the inferior angle of the left scapula, never that of mitral stenosis. This, he thought, was proof of the fact that the current of blood which created the murmurs was passing in opposite directions.—Dr. DICKINSON (St. George's Hospital) thought the murmur was due in this case to mitral regurgitation. He had pushed his finger deeply into the intercostal muscles, and had felt the contracting wall of the ventricular wall before it reached the chest wall, and he heard the murmur beginning with the appearance of the ventricular impulse. He could not accept Dr. Drummond's view that the impulse was derived from the contracting right ventricle, nor did he think that any help could be got from the hypertrophied condition of the wall of the left auricle, to which Dr. Oliver had

Digitized by Google

Whilst admitting with Dr. Finlay that the murmur of mitral regurgitation was frequently heard at the inferior angle of the scapula, he had also heard there the murmur which other observers had spoken of as presystolic. He thought that the conduction of the murmur to the angle of the scapula depended upon the volume of blood that was regurgitating through the mitral orifice.

Owing to the length of the discussions, Dr. Mantle's paper on Traumatic Tetanus and Dr. Limont's paper on Adenoid Vegetations of the Pharynx were taken as read.

Notices of Books.

St. Thomas's Hospital, Southwark. Part 2. By W. RENDLE, F.R.C.S. (Reprinted from the Transactions of the Royal Society of Literature.)—This interesting pamphlet is a continuation of "a short sketch history of St. Thomas's Hospital in Southwark, from about A.D. 1200 downwards, chiefly from original manuscripts," which we were able to notice favourably at the time of its publication a few years ago. The hospital seems to have borne several names. Mr. Rendle says—"I may note the changes, according to the whim of the time, in the name of our hospital. The Hospital of St. Thomas Overy—that is, of Thomas of Canterbury, less respectfully 'Bekket's spyttell'; the Hospital of the Holy Trinity; speedily changed, out of compliment to the generous re-founder, Edward VI., to the King's Hospital; and finally, and as it is now, the Hospital of St. Thomas the Apostle." Here is a picture of a hospital staff more than three hundred years ago: "In 1571 a 'phesyssion,' Mr. Bull, is appointed at a salary of twenty marks by the year, and to have a house in the Close; he acts as general doctor, superintends the apothecary and his drugs, but professionally is in a position subordinate to an official governor who has no pretence to a knowledge of medicine. The surgeon is at this time not much more than a curer of sore heads and a mender of broken bones, and has for competitors outsiders, curers of sore heads and bone-setters. The surgeon, as we see, works under the pressure of having his unsuccessful cases handed over to them, who *if they cure* are paid—an early instance of the 'no cure, no pay' system. In 1632 the apothecary is side by side with a herb-woman who has £4 a year for physical herbs. In 1652 a midwife is paid 2*s.* 6*d.* for her help to two poor women; long before Mother Edwyn engages to cure a boy of hernia for 13*s.* 4*d.*, half of which she will return if she fails." The surgeon comes in the list of officers between the shoemaker and the barber, and even in 1647 was not allowed to prescribe medicine, that function being restricted to the physician, who, however, in common with his surgical colleague, appears to have been considered as of infinitely less importance than not only the treasurer, but the cook, the butler, and the shoemaker!

Four Months among the Surgeons of Europe, being a series of letters to Dr. Chr. Fenger. By N. SENN, M.D., Ph.D., of Milwaukee, Wis., Chicago. 1887.—These letters were originally published in the columns of the journal of the American Medical Association, but they are well worthy of being reprinted in a separate form. They describe in a brief and pithy way what Dr. Senn saw in a four months' tour among the surgeons of Europe, and they are very useful as affording a picture of contemporary surgery. Dr. Senn is evidently a keen critic, but not an unkindly one, and his judgments are not warped by preconceived notions, by prejudice, or by the dictates of authority. At one time we find him speaking enthusiastically of a young and unknown worker, and at another running away from Thiersch because he had nothing to teach him. Dr. Senn was evidently not greatly impressed with London surgery, and he gives a painfully detailed account of an operation he witnessed. But it is only fair to add that Dr. Senn did not devote sufficient time to London, and he did not visit several of the principal hospitals, or meet many of the leading surgeons. The letters are very frank, written as probably only an American enjoying a "good time" could write them, and readers will get many a laugh from them.

Alassio: a Pearl of the Riviera. By Dr. JOSEPH SCHNEER. Pp. 80. London: Trübner and Co. 1887.—The author states in the introduction that his sole desire is to attract to this "Pearl of the Riviera" the attention of those who seek, far from the noise and bustle of the great world, a peaceful retreat amid lovely and romantic scenery. The book therefore is mainly a guide to Alassio, giving its history from the earliest periods, a description of its present condition, and an account of the various charming and easy excursions which may be made from it. The only specific information relating to its climate is contained in five pages of meteorological observations. It is, as we know, a beautiful spot, but there is little said of its sanitary condition, which, we fear, is not up to the mark. On the important subject of water the author remarks: "There is still much to be done in Alassio for the provision of a proper supply of water. Spring water is only to be had at particular spots, and the inhabitants have to content themselves for the most part with pumps. Financial difficulties have hitherto stood in the way of the laying down of pipes in order to bring a proper supply of water into the town."

The Influence of Sex in Disease. By W. ROGER WILLIAMS, F.R.C.S., Surgical Registrar to the Middlesex Hospital, Surgeon to the Western General Dispensary. London: J. and A. Churchill.—Mr. Williams has in this little work brought together a number of facts collected from the reports of the Middlesex and other hospitals bearing on the influence of sex in disease. He has compiled tables showing the diseases which affect each sex specially, in which the diseases are arranged in the order indicating relative liability. The table of female affections begins with those of the generative system and ends with phthisis, while the corresponding table for male affections commences with stricture of the urethra and ends with apoplexy. Regarding typhoid, the late Dr. Murchison believed the sexes equally liable, but, according to Mr. Williams, more males than females are attacked; on the whole, however, more females die, they being more liable to the accident of perforation than men.

Too Curious. A Novel. By EDWARD J. GOODMAN. London: Richard Bentley and Son. 1887.—The late John Stuart Mill foresaw the day when music would cease to be composed, as every possible combination of sounds had already been put together. In like manner certain critics of the "present state of the novel" are recommending young authors to try romance, as the novel of real life is dying of inanition from the exhaustion of its materials. "Too Curious" is Mr. Goodman's answer to these gentlemen. He has shown that, by making no greater demand on the credulity of his readers than others of his contemporaries, he can construct a fresh and interesting novel of real life from the people and the events that live and move around us. For the medical public "Too Curious" has special interest, not only for its sketches of hospital interiors and of every-day practitioners—Dr. Redmond is a character in point,—but for the happy use it makes of the phenomena of disease, especially of hysteria and catalepsy. Let any of our prolific young novelists do as Mr. Goodman has done—make a study of pathology as it affects real life,—and a whole world of interesting "developments" in character and situation will be revealed to him for the exercise of his flagging invention. We are not going to unravel the plot of "Too Curious." We shall have done enough if we have sent our readers to a novel of contemporary life which touches at many points on t

Digitized by Google

profession and its subject-matter, and which is not only of keen interest as a narrative, but is written in a flowing and graceful style which enhances the pleasure of its perusal.

Illustrations. Edited by FRANCIS G. HEATH. London: W. Kent and Co.—This volume, as one of the books of the season, is worthy of praise. The engravings, as a whole, are really excellent, whilst the articles are undeniably sound and good. It is not easy to conceive of a more fitting new-year's gift than this book would prove to an intelligent juvenile of either sex, and persons of more mature growth might well occupy a little leisure in scanning its pages.

ANNUAL REPORT OF THE MEDICAL OFFICER OF THE LOCAL GOVERNMENT BOARD.

[SECOND NOTICE.]

RECALLING the circumstance that the subject of scarlatina and its relation to disease in bovine animals, which forms an important part of Dr. Buchanan's last report, was largely dealt with in our issue of Dec. 17th in connexion with Dr. Klein's and Professor Crookshank's papers, and reminding our readers that the discussion on the subject at the Epidemiological Society will take place on January 11th next, we pass over that portion of the present report which deals with that subject and go on to advert to some of the other more purely scientific labours that are recorded in the volume.

The subject of tubercle has long been one which demanded the closest investigation in relation to public health, and owing to the allegation, during recent years, that the use of the milk of cows suffering from tuberculous disease was calculated to induce that disease in the human subject, it has become more than ever imperative that the department, having, as a duty, to maintain a general supervision over the health of the country and to guide sanitary authorities in their action, should do all it can to elucidate the circumstances under which this important infection may be communicated and spread. On the one hand, we have the serious fact that a large number of otherwise good milch cows are tuberculous, especially those which are stall fed and are kept in towns; and on the other, the more hopeful aspect of the case, that so far there is no evidence of tuberculous infection in milk itself. Dr. Klein and Mr. Lingard have made further investigations into the etiology and pathology of tuberculosis. In the direct inoculation of fowls with both human and bovine tubercle, the results now obtained are found to differ somewhat from those previously recorded. As to human tubercle, the last experiments show that it has been less readily communicable to fowls, and it can as yet only be suggested that this may be due to a difference of breed experimented on. Out of eighteen fowls infected with bovine tubercular matter five developed well-marked tubercle; whereas on the former occasion four fowls experimented on proved all of them refractory to bovine tubercle. The reversal in this case, too, may perhaps be due to the fact that the fowls last used were of a different breed to those used formerly, and this question of breed raises considerations that will have to be further examined into. Other experiments, made with a view of ascertaining whether tubercular virus by its passage through the fowl undergoes any and what alteration of virulence, go to show that by its passage through the fowl the bovine tubercular virus gains, so far as the fowl species is concerned, in virulence, fowls becoming more susceptible to it, and developing it in an exceptionally short time. It has also been ascertained that, just as in other constitutional affections the marrow of bones tends to become seriously implicated, so as regards tubercle the marrow is the seat of the earliest manifestation of induced general tuberculosis, the red marrow of long bones of rodents becoming affected before any deviation from normal conditions can be detected in any of their tissues and organs remote from the point of experimental inoculation. We have here an addition to the knowledge which pathology has supplied as regards this disease for the purposes of preventive medicine, and we find in it a further inducement to proceed with the investigation of an infection which is so widespread and so fatal in this country.

Dealing with the question of protection against infection by the agency of fluids in which infective bacteria have grown, Dr. Wooldridge records that he has obtained a "fibrogen" in which he has grown the anthrax bacillus, and after having separated the organism from the fluid in which it has grown, he is able, by introducing this fluid in considerable quantity into the venous system of an animal, to prevent the development of anthrax in its virulent form when the poison is simultaneously introduced under the skin. In fact, he hopes that he may be able soon to produce a fluid that can be trusted to furnish with constancy a complete protection against inoculated anthrax. "These researches on anthrax," writes Dr. Buchanan, "have to be regarded as introductory to observations on the material of other diseases, and the whole may be expected to be of the highest practical importance to preventive medicine."

Professor Cash, in continuing the researches as to the value of certain disinfectants, and using for his experiments the contagia of anthrax and of tubercle, finds, as regards the disinfecting abilities of chlorine, bromine, and iodine, that the degree of dilution of the agent and the thoroughness of the exposure to its influence constitute elements in the destruction of morbific properties which several viruses possess; and, estimating the relative potency of the several agents, he finds that the three agents do not show any very remarkable difference the one from the other, though iodine appears the most, and chlorine the least, potent. Both as regards these substances and sulphurous acid, Dr. Cash finds reason to prefer solutions to gases; but if a disinfectant in a gaseous form is needed, then he prefers that it should be sulphurous acid. To one important point in Dr. Cash's report Dr. Buchanan desires to give prominence—namely, where he "points out afresh the consideration, too often lost sight of in practice, that, inasmuch as quantity of the disinfectant counts for so very much in the destruction of any disease-producing material, it is necessary to take account of the assimilation, by harmless material, of the agent designed to disinfect; wherefore the quantity of the disinfectant used must be proportioned to the amount of such other material, as well as to the amount of actual morbid matter to be destroyed."

Further experiments are in progress by Dr. Klein as to the disinfection of pathogenic organisms by perchloride of mercury, he seeking to recognise the limits of attenuation available for practical use, so as to give insusceptibility to animals to whom the virulent infection of anthrax may subsequently be introduced; he is also extending similar researches to other bacilli, and to the micrococcus of scarlatina. Research is also being made into the chemistry of potable waters, with especial reference to the life history of their contained organisms; but these, together with certain related biological observations, are not yet ready for publication.

Taken as a whole, the volume under consideration must be regarded as one of the most important ever issued. Some of the matters dealt with in it, and notably that of metropolitan small-pox isolation, have been brought to a stage at which they need to be dealt with administratively, and a strong public demand in this direction can hardly fail to arise, unless the initiative is taken by those who now have the matter in hand. London must not go on blindly spending its thousands sterling on these hospitals without knowing absolutely and definitely where it is drifting. The stage reached as to the question of scarlatina and of tubercle in its relation to disease in the lower animals, is also one of grave importance to the public health; and it is clear that, if ever there was a time when the State should prosecute further research into the etiology of infectious diseases, it is the present one. The other labours we have adverted to have a different bearing on the prevention of such diseases, but the knowledge already acquired is of the utmost importance, and it promises the best results in its application to the promotion of public health. We wish that the State could understand how the prevention of disease would be advanced by placing this and similar official records in the hands of all medical officers of health, for it is of the first importance that local advisers should be placed in possession of the most recent scientific information bearing upon the duties they have to perform.

FATAL FOOTBALL ACCIDENT.—While playing on the 28th inst. at Abercarne, a football player was struck by the ball in the abdomen, and, falling to the ground, immediately expired.

THE LANCET.

LONDON: SATURDAY, DECEMBER 31, 1887.

THE ANNUS MEDICUS 1887.

Introductory.

THE year 1887 will be memorable in English history as the year of the Jubilee of Her Majesty Queen VICTORIA'S reign. Few arts have undergone greater development in this period than that of Medicine. In the history of Medicine itself there have been few epochs more signal than the half-century just closed, which has seen the introduction of anæsthetics, of the antiseptic treatment of wounds, of the pregnant discoveries of the part played by living germs in many diseases, and the recognition by the State and by Local Authorities of great responsibilities for the prevention of disease. This aspect of the time that is so inseparably associated with Her Majesty's reign has naturally been recognised by the various medical authorities of the kingdom. We, too, recognise it with gratitude and with pleasure, as we do the obligations of Scientific Medicine to Her Majesty and her illustrious family for constant favour and help. The year itself has not, perhaps, been signalised by any startling additions to medical knowledge, but our columns show signs of unabated energy in the profession, mingled with more care and painstaking in practice and in medical reasoning than at any prior period, with growing hopefulness and success in the treatment of hitherto almost hopeless forms of disease.

Anatomy and Physiology.

The subjects of Anatomy and Physiology have been illustrated and enriched by many original papers—the majority, as usual, proceeding from the indefatigable German workers.

In Anatomy, GRAPOW has given an excellent description of the palmar fascia in the *Archiv f. Anatomie und Physiologie*—a subject that is of great importance from a surgical point of view, and one which received the special attention of DUPUYTREN. In opposition to the statement generally made in works on anatomy, that the radicles of the venæ portæ are destitute of valves, HOCHSTETTER has demonstrated their presence in the vasa brevia of the stomach, which, however, is not perfectly new, since their occurrence in these vessels has been noted by both BAUER and SAPPEY. HOCHSTETTER gives a good description and accurate drawings of them. The muscles of the external ear have been carefully worked out by TATAROFF, and the vena saphena magna has had a long chapter devoted to it by KARL KLOTZ, dealing especially with the arrangement and disposition of its valves. BRAUNE and FISHER have published an elaborate series of tables, the result of much labour, giving the length of the fingers and metacarpal bones of the human hand.

In Physiology, Dr. WOOLDRIDGE has demonstrated the remarkable influence of the stroma of red blood-corpuscles on the coagulation of the blood, for if this be isolated by the action of an ethereal solution of an alkali and subsequent precipitation by acid, and be again dissolved in a little alkali, a fluid is obtained which, when injected into the veins of an animal, causes extensive and often fatal coagulation of the blood. On the other hand, the solution of the red colouring matter has no influence on coagulation. The remarkable action of the stroma of the blood-corpuscles appears to be due to the presence of lecithin. The observations of LANGLEY and EDKINS on pepsinogen and pepsin show that alkalies have a very destructive influence on pepsin, so that when equal parts of a solution of pepsin and a 1 per cent. solution of soda are mixed, one-half of the pepsin disappears in the course of fifteen seconds. Even a solution containing only 1-5000th of soda will in the course of an hour and a half destroy a considerable quantity of pepsin. Pepsinogen is similarly but less powerfully acted on. Acids rapidly convert pepsinogen into pepsin, and this process probably goes on in the act of digestion. Electrical stimulation of the intestines of the rabbit by constant currents has been shown by SCHILLBACH to cause active contraction of the duodenum, moderate contraction of the lower part of the small intestine, and slight contraction of the cæcum. The effects of the induced currents are much less active; the part near the anode contracts most powerfully. He has applied his experiments in cases of constipation, and has been successful in causing defecation in man by applying the cathode to the rectum and the anode to the abdominal wall. A new acid, crystallising in rectangular tablets from its ethereal solution, has been discovered by SCHOTTEN in human bile, and named fellinic acid. It gives a bluish-red tint with PETTENKOFER'S test. DEMANT finds that the quantity of glycogen contained in the liver of newly-born puppies killed by bleeding amounts to 11·4 per cent., which in the course of the few following days rapidly diminishes, so that at the expiration of eleven days it had fallen to 2·8 per cent., that of the adult dog fed upon bread and meat amounting to 1·66 per cent. LOWRY has demonstrated by experiments conducted in ZUNTZ' laboratory that respiratory movements, though much reduced in degree, still continue after complete isolation of the respiratory centre by sections carefully made through the spinal cord and medulla oblongata, which shows that the passage of non-oxygenated blood moving to the centre is alone required for respiration to be maintained. Many papers have been written on the nervous system. BORGHERINI, in curious opposition to BROWN-SÉQUARD, finds that the central grey matter of the spinal cord is incapable of conducting impressions. Section of the lateral columns he found to cause complete paralysis, notwithstanding that the anterior columns were preserved, which he attributes to the circumstance that the anterior columns gradually acquire the powers of conduction as collateral paths. SCHÄFER has repeated FERRIER'S experiments on the motor areas of the cerebral cortex in dogs, and in the main supports the conclusions arrived at by FERRIER, though somewhat extending and modifying his regions; he believes the regions to occupy the same or nearly the same relative areas in different brains. ASCH and NEISSER have endeavoured to ascertain the precise depth of the cells from which motor impulses emanate, and believe that it corresponds to that layer which is situated just external to the junction of the grey and white matter of the cortex

Digitized by Google

cerebri. Von MONAKOW draws the conclusion from his experiments on rabbits and cats that the striæ acusticæ are to be regarded in great part as secondarily decussating paths of conduction of acoustic nerves, whilst the inferior loop constitutes the main central path which acoustic impressions pursue in their course to the brain. Dr. C. F. MARSHALL has published in the *Quarterly Journal of Microscopical Science* some new views of the structure and mode of contraction of striped and unstriped muscle. He considers the contractile part of muscle to consist of a very regular and highly modified intra-cellular network, and that contraction is caused by the active contraction of the longitudinal fibrils of the intra-cellular network, whilst the transverse networks are passively elastic, and by their elastic rebound cause the muscle to rapidly resume its relaxed condition when the longitudinal fibrils have ceased to contract. He thinks the transverse fibrils may also possibly be paths for the nervous impulse. Dr. MCWILLIAM of Aberdeen believes he has been able to demonstrate that a single muscle contraction, such as accompanies the knee jerk, is attended by a distinct sound—a point of considerable importance in regard to the causation of the first sound of the heart. KÜHN has continued his researches on the mode of termination of motor nerves, the most important result of which is that he has satisfied himself there is absolute discontinuity between the tissue of the nerve and that of the muscle in which it ends, so that there is no fusion at any point. MARCUSE'S experiments show clearly that during muscular activity lactic acid is formed at the expense of glycogen, whilst those of BOEHM prove that in rigor mortis the formation of lactic acid takes place without any diminution in the quantity of glycogen. The lactic acid normally formed in contracting muscle is destroyed at the liver. Ganglia and ganglionic nerve cells have been found by KASEM-BECK in various animals, though not in man, on the surface of the left ventricle. The cells are unipolar, pyriform, with granular protoplasm and a peripherally situated nucleus. In the calf, he has observed them, in a heart 80 mm. long, within 5 mm. from the apex. OTT was also unable to find any ganglion cells on the ventricle in man, but finds that they are abundant in the septum atriorum. A valuable paper on the Action of the Excised Mammalian Heart was contributed at the very close of last year to the Royal Society by Dr. AUGUSTUS WALLER and Mr. E. W. REID. They obtained tracings from rabbits' hearts of spontaneous beats for no less than seventy-two minutes, and of beats in response to excitation for an hour and a half after death. As a rule, the decline was found to be fairly regular as to force and frequency of contraction, and the contractions not unfrequently presented a trigeminal character. In the first few minutes after excision the sequence of auriculo-ventricular action was normal, but at a later period several auricular beats occurred to one ventricular beat. The duration of the ventricular beats after excision became prolonged from the normal 0·3 of a second to six seconds. They found also that the heart, when excised and cooled, presented some remarkable phenomena in regard to its contraction—the latent period, for example, being prolonged to as much as two seconds. Lastly, they established, by connecting two levers with the heart at its base and apex, and obtaining tracings on a revolving drum, that there is in the heart, as in other muscles, a wave of contraction the rapidity of which in the sheep was eight metres per second. The histological researches of BAUM on the cells of the liver of the horse, three, five, thirteen, thirty-six, and forty hours after food, show that in the state of rest the nuclei of the cells can be stained with hæmatoxylin; the contours of the cells are indistinct. They contain granules and vesicular eosinophilous structures, and but little glycogen. In the active state the cell contours are distinct, the nuclei are often absent, the protoplasm contains much glycogen, and the pigment granules are few. BAUM believes, from micro-chemical tests, that the cell nuclei form the biliary constituents, and the cell bodies are glycogen producers. KABRHEL'S experiments on the excretion of colouring matter, such as indigo-carmine, support the views of HEIDENHAIN in regard to the activity of the cells of the convoluted portion of the lobes in effecting the excretion of such substances, and by inference their function in eliminating certain constituents of the urine. The reaction time for sensations of temperature has been made a special subject of investigation by GOLDSCHEIDER. The temperatures experimented upon were 15° and 50° C., and it was found that the reaction time of the face was for cold 13·5 hundredths of a second, and for heat 19 hundredths; the upper extremity, for cold, 15 hundredths, and for heat 27 hundredths; the abdomen, 22·6 hundredths for cold, and 62 for heat; and the lower extremity 52·5 hundredths for cold, and 79 for heat.

Pathology.

Year by year it is becoming more apparent that the aims of pathological research are changing. The spirit of inquiry is penetrating beyond the detection and description of the characters of morbid lesions and the explanation of tissue changes. It is concerned now largely with etiological considerations—a long step further back than mere morbid anatomy or physiology. Hence arises the important position which is being rapidly assumed by bacteriology, and the interest attaching to its pursuit. Amongst the evidences of the widespread activity in this department may be taken the success which has attended the publication of a *Centralblatt für Bacteriologie und Parasitenkunde*, which commenced with the opening year, and appears every week full of matter referring to bacteriological research. There should be mentioned also the issue of the first part of Professor KLEBS' "General Pathology," which is devoted to the exposition of these etiological considerations, and the appearance of new editions of CORNIL and BABES' classical treatise, "Les Bacteries," of Professor CROOKSHANK'S "Manual of Bacteriology," and similar works by HUEPPE, FRAENKEL, and others. Regarding—as one is forced to do—the researches in this department as forming the vanguard of pathology, one may without hesitation assign the most important place in the year's work to the investigations into the etiology of Scarlet Fever carried on almost simultaneously by Dr. KLEIN in London and Dr. [illegible] in Edinburgh. The subject matter of their [illegible] is so fresh in the memory of our readers that [illegible] sary to treat it in detail. Suffice it to say [illegible] succeeded in obtaining from the discharges [illegible] udder and teats of cows, to whose milk M[illegible] the source of an epidemic of scarlet fever,

Digitized by Google

which he subsequently isolated from the blood of scarlatinal patients; whilst, as to Dr. EDINGTON'S study of the microbes of scarlet fever, not only were various forms of microbe found but a bacillus, which was discovered in the blood before the third day, and in the desquamating cuticle at a later period. Dr. KLEIN was unable to confirm Dr. EDINGTON'S observations, and a committee of the Edinburgh Medico-Chirurgical Society reported that further evidence was needed before concluding that the bacillus was pathogenic and specific. Cognate to these researches is the very recent investigation of Professor CROOKSHANK into a contagious malady of cows, which he believed was identical with the disease investigated by Dr. KLEIN, which, according to Professor CROOKSHANK, yielded the same microbe, but with which no scarlatinal connexion could be traced. Dr. KLEIN disputed the identity of the two cow diseases, whilst Professor CROOKSHANK adduced strong evidence in support of the cases he examined being vaccinia. Several points of importance to the public health arise out of these inquiries, and we are probably on the threshold of an investigation which may prove to be of the greatest consequence. Towards the close of the year, also, it was announced from Berlin that Dr. SCHEUERLEN, assistant to Professor LEYDEN at the Charité Hospital, had discovered the "bacillus of cancer." That cancer may depend upon the presence of a microbe in the tissues has been of late years suggested in more than one quarter; but by none has the hypothesis been more philosophically or lucidly stated than it was by Sir JAMES PAGET in the Morton Lecture, delivered at the Royal College of Surgeons on Nov. 11th. Sir JAMES contrasted the mode of origin and development of cancer with that of other specific diseases, and considered the analogy close enough to warrant the inference that some "morbid substance," "microbe or ptomaine," was the source of the tissue change. However, such careful investigators as Messrs. BALLANCE and SHATTOCK reported to the Pathological Society their cultivation experiments upon morbid growths, which all yielded negative results; and in all quarters there is a tendency to accept SCHEUERLEN'S statements with reserve. The subject of Cholera has been enriched by the publication of von PETTENKOFER'S recent writings; and during the year there was issued the report of the English Commission sent in 1885 to Spain to study the subject. The conclusions arrived at were not very definite, but a new and hitherto undescribed micro-organism was reported to have been constantly found in the dejecta and intestines; whilst the comma bacillus was suggested to be a concomitant of the premonitory diarrhœa. It may be added that the practical value of the comma bacillus as a means of diagnosis of Asiatic cholera has been successfully tested in an outbreak on board an Italian emigrant ship which arrived at the port of New York. The Pasteurian treatment of Hydrophobia has been much criticised both in the Paris Academy of Medicine, chiefly by M. PETER, and in articles and monographs by various writers. The report of the English Commission was, on the other hand, highly favourable to the method adopted by M. PASTEUR, although it recommended stringent police regulations rather than the institution of preventive inoculation. The ever-interesting subject of Fever was discussed by Dr. MACALISTER in his Gulstonian Lectures, which treated it mainly as a question of the nervous mechanism concerned in heat production, regulation, and loss; and also by Professor AUSTIN FLINT before the Washington Congress, who rather avoided that line of inquiry and dealt with the febrile state from the metabolic standpoint, with especial reference to its treatment. Mr. NORTH, the Research Scholar of the Grocers' Company, gave a course of lectures upon Malarial Fevers, based upon his studies of these diseases in the Campagna, and devoted part of his course to the subject of their pathology. Beri-beri has been studied by several writers, including an interesting report by Dr. KYNSEY of Ceylon, identifying the disease with anchylostomiasis. Actinomycosis hominis has received fresh elucidation at the hands of Dr. MARKHAM SKERRITT and Dr. HEBB. Syphilis, with especial reference to its microbes, has been studied by BENDER and DOUTRELEPONT; and LUSTGARTEN'S bacillus, although sparsely distributed, has mostly been recognised. The connexion of microbes with Tetanus has received much attention in the contributions of ROSENBACH, HOCHSINGER, and SHAKESPEARE. Endocarditis has been studied by FINKEL and SÄNGER, who found micrococci in the diseased valves in several cases, the chief forms being staphylococci; and by PRUDDEN, who published details of a careful study of one case of mycotic endocarditis. KINNICUTT recorded a case of Pernicious Anæmia due to Atrophy of the Gastric Mucosa, and the same subject has received fresh contributions from HENRY and OSLER. Peripheral Neuritis has been described in Raynaud's disease by Dr. WIGLESWORTH, and further confirmation of its existence in association with tabes, diphtheria, and other diseases has been general. Dr. FINLAY contributed to the Royal Medical and Chirurgical Society a paper on Alcoholic Paralysis in which the existence of multiple neuritis was well shown. The paralytic sequelæ of fevers received an explanation in the carefully reported case by Dr. BARLOW of myelitis occurring in the exanthem stage of measles. Thrombosis has been studied by HANAU, EBERTH, SCHIMMELBUCH, and WEIGERT, chiefly as to the formation of the thrombus; whilst Dr. COLLIS WARREN published a careful memoir upon the Healing of Arteries after Ligature. Dr. METSCHNIKOFF has supplied fresh facts in support of his contention that phagocytes play a large part in morbid processes, particularly in diseases depending upon bacterial invasion. Mr. BLAND SUTTON continued at the College of Surgeons his lectures on Evolution in Pathology, and Mr. BOWLBY took for his subject that of Injuries and Repair of Nerves. Lastly may be noticed the appearance of a fifth edition of Professor ZIEGLER'S admirable text-book on Pathology, and the commencement of a new pathological serial (*Beiträge zür Path. Anat.*) under the editorship of Professors ZIEGLER and NAUWERCK, primarily intended as a medium for the publication of monographs based upon the researches carried on in the various continental laboratories.

Therapeutics.

If we may judge from the writings of the past year, the chief result of therapeutics has been to gratify the taste, rather than cure the diseases, of our patients. One most important fact is the free circulation of saccharine, brought about by manufacturing enterprise, which ever follows in the wake of physiological chemistry. Another important acquisition of the year has been the discovery that antipyrin and antifebrin are not only of value in reducing the tempera-

Digitized by Google

ture of fever, but also have the property of relieving many cases of nerve pain. Not one of the least important contributions to the study of antipyrin is that by ALBERT ROBIN, which recently appeared in the *Gazette Médicale*, No. 50. A great deal of attention has been given to the treatment of heart and lung disease. Strophanthus has had a more extensive trial in the treatment of heart disease, and very various opinions have been expressed as to its capacities for good; the general conclusion to be arrived at from an impartial study of what has been written must be that further experience is required before we can rightly appraise its value, if it has any, or before we can determine in which class of case it can produce the best effects. The treatment of lung disease by the rectal gaseous medication has had a fair trial. It has failed to sustain the reputation with which it was launched upon the medical world, at least in regard to pulmonary phthisis; and though it may be good in some cases of bronchial disease, yet other methods of treatment are at least as efficacious. Injections of carbolic acid and of hyperosmic acid have been employed, apparently with considerable success, in cases of chronic muscular rheumatism, and that uncertain affection or affections to which the name of sciatica has been attached by clinicians. In the treatment of Skin Diseases, especially of a limited character, the method of employing a varnish so ably advocated by AUSPITZ has met with increasing favour from dermatologists and others. The chief feature of the method is to form an artificial film or cuticle. A solution of one part of purified gutta-percha in ten parts of chloroform is known as traumaticine; it forms a softer and thinner film than gelatine and collodion, and, besides, causes neither tension nor pain. This matrix may be impregnated with chrysarobin in the treatment of psoriasis. The scales should be first removed by soap and water, and the solution painted on the affected parts with a thin short-cut pencil-brush. Dermatine made of copal dissolved in turpentine is a new and valuable varnish. The value of this method is largely due to the circumstance that the atmosphere is entirely prevented from assisting at the development of the skin disease, and there cannot be the shadow of a doubt that our atmosphere possesses in its chemical, mechanical, and bacterial impurities a great power for harm. Dr. SHOEMAKER contributed an article to our columns on "Rectal Alimentation and Medication in Diseases of the Skin." In cutaneous diseases suppositories are the most convenient form of medicating the system by the rectum, since they are more slowly absorbed than solutions; whilst the ease, cleanliness, and safety of administration more than compensate for their slightly retarded action, according to this authority. The nasal treatment of Whooping-cough by various substances of an antiseptic and anæsthetic kind is one which has found some favour with the profession in England. Of the value of cocaine in congested states of the nasal mucous membrane, everyone who has employed a strong solution has satisfied himself. The treatment of Gall-stones by the use of a decoction of a well-known fern—asplenium ceterach or doradilla—and also by very large doses of olive oil, is amongst the therapeutical singularities of the year; and there are grounds for believing that each of these remedies may be found of value. On the theory that Asthma is due to spasm of the involuntary muscular tissue of the bronchial tubes, Dr. FRASER of Edinburgh tried the action of nitrite of amyl and other allied bodies. He watched the progress of the physical signs whilst these substances were operating in the system. Considerable success attended this treatment. The nitrite of amyl was given in solution, five minims in two drachms of water, or inhaled, ten minims on blotting-paper at the bottom of a small glass tumbler. The nitrite of ethyl—nitrous ether—acts well in ten-minim doses of a 25 per cent. alcoholic solution. Of the nitrite of sodium ten minims of a 10 per cent. solution, and of the nitroglycerine five minims of a 1 per cent. solution, were employed. The use of the nitrites is well known, but perhaps not so widely practised as could be wished for the welfare of our patients. The treatment of Cancer has not unnaturally been the subject of much writing in our columns, both from contributors and by ourselves. We must not despair of discovering a means for checking the growth of malignant diseases, and, in the words of Sir JAMES PAGET, "we might well be nearly content if we could find a medicine as efficient against cancer as mercury and quinine are against syphilis and ague, especially as the recurrences of these diseases are less, not more, severe than the primary." Not one of the least valuable therapeutical attempts of the year is the treatment of the "Green Diarrhœa" of infancy by means of lactic and other acids, based presumedly on the belief that this complaint is due to the growth of a chromogenic bacillus.[1] The uses of Cocaine have become better understood, whilst its employment has been extended to every department of disease, but that it must not be recklessly employed is the lesson to be learned from a consideration of the serious symptoms to which its hypodermic injection occasionally gives rise.

Papers on the treatment of Phthisis have appeared frequently in our columns, dealing with the subject from many points of view. We have already referred to the BERGEON method, but of far greater importance than it are the contributions which we have published on the climatic and antiseptic modes of treatment. Morrhuol is another product which deserves some mention, for great expectations have been raised by its introduction into therapeutics as a substitute for cod-liver oil possessing twenty-five times its weight of the crude medicament. We would draw particular attention to our articles, by a special correspondent, on the High Altitude Treatment of Phthisis. Sparteine and Nitro-glycerine have been found by Dr. OSCAR JENNINGS to have the property of relieving the craving for morphia in morphinomania. The paper on the Treatment of Typhoid Fever by the cold wet pack and alcohol, from the pen of Dr. CURNOW, was a valuable contribution to our pages at the commencement of the year. The method of employing fluid vaseline for Hypodermic Medication is coming into use in this country as on the Continent; it is contended that vaseline is absolutely harmless to the tissues, and may be employed in large doses without causing accidents, but the vaseline must be perfectly pure, which is shown by its not blackening with warm sulphuric acid. Various medicaments, such as eucalyptol, turpentine, iodoform, phenol, iodine, and camphor, may be dissolved in the pure fluid vaseline, and injected in the strength of 1 per cent. or

[1] Vide THE LANCET, p. 1029.

Surgery.

If we look back over a period of twenty, ten, or even five years, the chief advance in the healing art has undoubtedly been made in Surgery. Whatever else this generation has done or failed to do, it must ever be famous for the introduction of the antiseptic system of treatment of wounds, which has resulted in an enormous saving of life and limb and incalculable relief of suffering, and of the application of surgical measures for the relief or cure of affections formerly considered outside their domain. He would be a rash man who would undertake to maintain that this enlargement of the field of surgery has been an unmixed good obtained without any countervailing disadvantage. The very safety now attending properly conducted surgical operations may itself be a danger, and lead the surgeon to propose or carry out operations which are not expedient. But such cases are far outnumbered by the real trophies of the healing art, and it is only the jaundiced eye that would regard the one set of facts and ignore all the other side of the question. Looking back upon the year that is just closing, it would be difficult to fix upon any one new point or fact as especially the outcome of the work of the year. We cannot speak of any new organ being made amenable to surgical interference, mainly because surgeons have not in former years refrained from carrying their knives into every region of the body. Nor have we to notice the introduction of any new form of surgical dressing. The alembroth wool and gauze have continued to advance in favour, and both the spray and the gauze of the Listerian method are now rarely seen. That this is a gain who can doubt? To many men the discomfort of the spray is very great, and all are agreed that our present plan is a great improvement upon that which preceded it. New antiseptics have been described and recommended, but for the present bichloride of mercury holds the field, and deservedly. Not that anything approaching uniformity in the dressing of wounds has been obtained. Not only in different places and institutions, but even among colleagues in the same hospital, marked divergencies in the plan of treating wounds may be witnessed. There is nothing new to record in cerebral surgery; it is not likely to advance in leaps and bounds, and the difficulties often attending the diagnosis of cerebral affections, as well as the serious late results in some cases of operation upon the brain, have deterred many surgeons from practising it. Very extensive operations have been performed upon the unyielding chest wall in cases of chronic empyema, and on the whole with very satisfactory results. The success of this operation largely depends upon its completeness, for if the unyielding part of the wall of the suppurating cavity is not wholly excised, so that its complete collapse is not ensured, a sinus is very apt to be left behind. Abdominal surgery is "consolidating" its progress. Laparotomy has recently been practised for tubercular peritonitis, and with such favourable results that it deserves a further trial. A suspicion has long existed that in some quarters laparotomy has been resorted to too often, and on insufficient grounds, and the events of the year have not dispelled this suspicion; but we seem to be approaching the time when the dazzling effects of the brilliant success of abdominal operations will have passed off, and surgeons will be able to judge more justly of their value and applicability. Many cases in our columns have attested to the strong position supra-pubic cystotomy now holds, for the removal of both large stones and of tumours. Its more extended practice has only increased the confidence felt in it when performed under the new conditions now universally laid down. Formal excisions of joints are becoming less popular, and arthrectomies, with very careful removal of all diseased structures, are largely taking their place. This is a change for the better, as many of the bad results of excisions are due to a desire to conform to the recognised mode of performing the operation, and the failure to remove all the diseased parts. Nevertheless, excision has been applied with success for the cure of hammer-toe and eversion of the great toe or bunion. Iodoform injections for cold abscesses have been found successful in many cases, and are certainly worthy of trial. Interest is still felt in the value of Chian turpentine in cancer; the most contradictory evidence as to its merits has recently appeared in our columns, and in the face of it Prof. CLAY has still to make his position good.

Ophthalmology.

The interests of ophthalmological science have been promoted by the Congresses at Heidelberg, Dublin, and Washington, at each of which places numerous memoirs were read and excellent discussions maintained. The Ophthalmological Society of the United Kingdom were fortunate enough to secure the services of Professor ZEHENDER to deliver the Bowman Lecture at the close of 1886, who discussed and showed the progress that had been made in regard to our knowledge of the parasites of the eye since the publication of the last edition of MACKENZIE'S work in 1844. The Society have also published the seventh volume of their Transactions, which is not inferior to its predecessors, though it would perhaps be improved by the inclusion of more papers like that with which it opens, on toxic amblyopia. A remarkable observation has been made by ONODI of Buda Pesth—namely, that neither in dogs nor in rabbits will the introduction of gonorrhœal pus excite any inflammation, nor can inflammation be induced even if the surface be wounded; but if the animal happen to suffer from catarrhal conjunctivitis, then the inoculation of gonorrhœal pus will immediately excite an acute attack of gonorrhœal ophthalmia, as though the condition of catarrhal inflammation weakened the power of resistance of the cells to external noxious influences. The question so much discussed some years ago in regard to the participation of the fixed corpuscles of the cornea in the process of inflammation has again been made the subject of experiment by HOFFMANN, who finds, on irritating the cornea of cats, rabbits, guinea-pigs, and frogs, and the subsequent application of strict antiphlogistic remedies (so that suppuration was entirely prevented), that complete reparation with restoration of transparency occurred, through the agency of the proliferation of the true corneal corpuscles; whereas when suppuration took place cicatricial tissue was invariably produced. Von HIPPEL of Giessen has been very successful in his efforts to effect transplantation of the cornea, being able at the Heidelberg Conference to exhibit to the Society a man who had been operated on twenty-seven months previously, and

Digitized by Google

who could still read large type. An important memoir has been published by R. DEUTSCHMANN on Optic Neuritis and its relation to Intra-cranial Disease. The optic neuritis that accompanies coarse disease of the brain has sometimes been attributed to augmented pressure, but the experiments of DEUTSCHMANN show that injections of agar-agar into the subdural space, or run into the sheath of the optic nerve itself, will not produce true optic neuritis, whilst the injection of staphylococcus microbes quickly induces that condition. He therefore holds that optic neuritis has nothing to do with increased intra-cranial pressure, but is the effect of an inflammation-exciting microbe, which passes from the cranial cavity with the cerebro-spinal fluid into the sheath of the optic nerve. EXNER and PANETH adduce experimental evidence to show that the visual area of the cerebral hemispheres is not limited, as some maintain, to the occipital lobes, for they find, in dogs at least, that injury to the sigmoid gyrus is in almost all instances followed by a crossed impairment of vision UHTHOFF has had large experience in the effects of the abuse of alcohol on vision, and finds that complaint is usually made of amblyopia. In 63 per cent. of cases the temporal half of the disc presents abnormal pallor, and in those cases where the amblyopia had existed for more than six weeks this symptom was almost universally present. The cause of the amblyopia is retro-bulbar neuritis. In alcoholic amblyopia central scotoma for red and green, and in many instances for blue also, is of common occurrence. There seems to be a general disposition to omit the performance of iridectomy in the operation for extraction of cataract. SCHWEIGGER, LANDOLT, POWER, SCHÖLER, and many others, now only perform an iridectomy when an untoward condition is present or some accident happens—as, for example, when adhesions exist between the iris and the lens, or when return of the iris is difficult, or when it has been injured and bleeds. The stimulation of any part of the brain cortex in cats and dogs with weak electrical currents, according to MISLAWSKY, invariably causes dilatation of the pupil, and this occurs even after section of the cervical sympathetic of the spinal cord at the level of the atlas, evulsion of the superior cervical ganglion, and division of the fifth nerve at the Gasserian ganglion. STOCKER has examined the influence of mydriatics and myotics in intra-ocular pressure, and finds that under normal physiological conditions atropine slowly diminishes the tension of the eye; cocaine in most cases first slightly exalts it, then lowers it; eserine acts in a similar manner to cocaine, except that the secondary depression is greater; pilocarpine also first increases, then lowers, tension.

Obstetric Medicine.

The past year has been productive of a large number of papers, many of which represent honest, earnest, and able investigation, and among such the following may be mentioned:—Stricture of the Urethra in Women, by Dr. HERMAN; a carefully recorded case of Galactorrhœa, by Dr. GIBBONS; a series of five papers on the Third Stage of Labour, by Dr. CHAMPNEYS (this subject has also engaged attention in Edinburgh); Hæmorrhagic Parametritis (parametritis, with hæmorrhage into the abscess cavity), by Dr. MATTHEWS DUNCAN; the Frequency of Pathological Conditions of the Fallopian Tubes, as observed in the post-mortem room of the London Hospital, by Dr. LEWERS; Retroflexion of an Early Human Embryo, by Mr. LOCKWOOD; a case of Cæsarean Section, by Dr. CULLINGWORTH; Tubo-ovarian Cysts, by Dr. W. GRIFFITHS; Diabetes Insipidus in Pregnancy and Labour, by Dr. MATTHEWS DUNCAN; three papers on Extra-uterine Gestation, by Drs. WILLIAMS, HERMAN, and CHAMPNEYS; Tonic Contraction of the Uterus, without Completeness of Retraction, by Dr. MATTHEWS DUNCAN; and two papers by Dr. HERMAN on cases of Eclampsia and Bright's Disease in Pregnancy, with careful analyses of the urine. In Edinburgh the study of frozen sections illustrative of the anatomy of labour continues to occupy much attention. The above record shows a healthy state of activity affecting workers of all ages and standing, and augurs well for the future.

Royal College of Physicians.

The universal esteem in which the present President of the College of Physicians is held was reflected in his election by the Fellows for the seventh time to fill that office. Largely owing to his efforts, the College resolved almost unanimously at the close of last year to endeavour to obtain in conjunction with the College of Surgeons powers to grant medical degrees. The movement was supported by memorials presented to the College from students and teachers of the metropolitan schools, and resulted in the framing of a petition to the Privy Council with a Draft Charter for the constitution of a Senate of Physicians and Surgeons which should have these powers. The petition was not presented until some months after it had been adopted by the College and in the meantime a scheme for establishing a Teaching University which originated from University College and King's College had been set on foot with similar but wider intentions. This point, however, is treated more fully under the heading "Medical Education" in another column, to which we refer our readers. Meanwhile the Conjoint Examining Board of the Colleges of Physicians and Surgeons has become more firmly established, and in a short time no students will be examined by either College separately for their diplomas. The examinations are entirely conducted at the Examination Hall on the Embankment, which has doubtless proved a great relief to the officials of each College; but it is questionable whether the withdrawal of the candidates from the previous practice of examination in a hospital ward is calculated to maintain the efficiency of the medical clinical examination. As regards the standard set by the Colleges, we have felt it our duty to draw attention to the remarkably high rejection rate at the final examinations; but how far this depends upon faulty education or defects in the system of examination itself it is at present not easy to decide. An important change has been made in the conditions under which the Croonian Lectures are to be delivered at the College of Physicians. It consists in the annual appointment of a Fellow of the College (who shall be eligible for re-election) to the office of Croonian Lecturer, whose duty it will be to deliver a course of lectures in June upon subjects which he has investigated in connexion with disease or its treatment. Dr. D. MACALISTER has been nominated by the President as the first holder of this office, and he will lecture next year upon the Pulse. The question of the buildings to be erected on the vacant ground behind the Examination Hall has

Digitized by Google

engaged the attention of the two Colleges, and the joint committee has decided upon a plan for providing a theatre and laboratories, which will shortly be presented to the Colleges for approval. The year of Jubilee was marked in the Royal College of Physicians by the presentation to Her Majesty the QUEEN of an address of congratulation, and by the resolution to erect a statue of Her Majesty in the Examination Hall. The Baly Medal was awarded to Dr. FERRIER; and the Harveian oration was delivered by Dr. STONE. The Bradshawe Lecture was given by Dr. S. WEST, who chose as his subject "Pneumothorax." Dr. MACALISTER delivered the Gulstonian Lectures on the Nature of Fever; Dr. BROADBENT, the Croonian, upon the Pulse; and Dr. PRIESTLEY, the Lumleian, on the Pathology of Intra-uterine Death. In the deaths of Dr. WILSON FOX, Sir GEORGE BURROWS (ex-President), and Dr. A. FARRE, the College has had to mourn the loss of three of its most distinguished Fellows.

Royal College of Surgeons.

In the year which has just terminated the College of Surgeons has manifested almost as much activity as in the year which preceded it, and this statement holds good not only of the Council, but also of the general body of Fellows and Members. Towards the end of last year the Council had issued a circular to the Fellows of the College, asking for their opinion on the following questions:—1. In your opinion should Members of the College be allowed to vote for Fellows as members of the Council? 2. In your opinion should Members of the College be eligible for seats on the Council? The result of this circular was announced to the Council at its first meeting. A definite reply was given by 700 of the Fellows, 419 voting "No" to the first question, and 276 "Yes," giving a majority of 143 "Noes." On the second question 526 voted "No," and 172 voted "Yes," the "Noes" having a majority of 354. We cannot, however, view the result of this polling as discouraging the demands of the Members and some of the Fellows to an extension of the franchise to Members of a certain standing. As the questions were put they did not mention those restrictions which the Members themselves would impose as a time-qualification of voters or candidates from their own body for seats on the Council. In combination with the Royal College of Physicians the Council of the College has applied for a Charter to give power for the Conjoint Board to grant degrees in Medicine and Surgery. The Council of the College of Surgeons has also applied for a Supplementary Charter, which does not include those alterations and amendments which were asked for at the general meeting of Fellows and Members in November of last year and previously, as the wish of the large majority then present. The resolutions which were passed at that annual meeting were again brought forward at the meeting of this year, and were forwarded to the Lord President of the Privy Council by the Council of the College at the request of the meeting. On Nov. 11th deputations from Fellows and Members waited on the Lord President of the Privy Council and placed their views and wishes before his lordship (see Second Edition of THE LANCET, Nov. 12th); they were courteously and favourably received, and on Nov. 23rd a letter was forwarded from the Lords of the Privy Council to the College, containing a copy of the statement relating to the Supplemental Charter prepared by the Association of Fellows, and "requesting any remarks thereon that the Council may have to offer." The reply to this will be given at the first meeting next year. Early this year he Conjoint Board took possession of the new Examination Hall on the Victoria Embankment, and the various examinations in connexion with the two Colleges are now held there, the College itself being deserted by those crowds of anxious students which were so marked a feature at stated periods of the year, excepting during that part of the examination (in General Surgery and Pathology) which is still held in the Library of the old College. We cannot but regret the decision of the Council to refuse admission to the Society of Apothecaries to the Conjoint Examining Board, in spite of a strong recommendation from the Medical Council; an opportunity of diminishing the number of examining bodies in London and the institution of a more uniform standard of examination for the majority of London medical students was lost which may never present itself again. The transfer of the ERASMUS WILSON bequest to the College has made it one of the richest of medical corporations, and has correspondingly increased the responsibilities of the Council, whilst it has placed it in their power the means to do more for the advancement of the science and art of surgery than any other body in the world possesses. Much money has already been spent on the College for building purposes; the Library and Museum have both been enlarged, and additional workrooms built, some of which are to be devoted to pathological investigation by Fellows and Members under the control of the Museum Committee. A pathological curator, to give his time to the pathological department of the Museum, is to be appointed next summer, and an additional assistant, to help in procuring, examining, and preparing pathological specimens, will be appointed early in the new year. And on the vacant space at the site of the Examination Hall a lecture theatre and other rooms are to be built in conjunction with the Royal College of Physicians. We would refer, in passing, to the delivery of the first Morton Lecture on Cancer and Cancerous diseases; this was given by Sir JAMES PAGET. Four Examiners in Public Health were for the first time appointed by the College with the consent of the Royal College of Physicians, and thus this most important branch of Medicine receives at last some acknowledgment of its usefulness. A notable event of the year was the election for the third time of Mr. SAVORY as President. This action on the part of the College has given general satisfaction, and it would be impossible to find anyone more capable of sustaining the dignity and honour of the College. In conclusion, we would refer to the opinion of the Council on a subject of the greatest importance to the profession—one which has been frequently brought forward in these columns and earnestly pressed on the attention of all—namely, the question of so-called "popular" medical teaching. Here there should be only one opinion; and the Council in the last resolution passed at the end of its year's labour resolved—"That, in the opinion of the Council of the Royal College of Surgeons, it is most objectionable that Fellows and Members of the College should allow their names to be advertised in connexion with medical or surgical subjects in popular journals."

Army, Navy, and Indian Medical Services.

The past year has been one of considerable disquietude in the Army Medical Service in consequence of a very unwise step taken by the War Office authorities. To get rid of some inconvenience which was experienced from the grant of "relative rank" to certain officers on the General Staff, it was abolished by Royal Warrant in January; and the abolition was extended to all the branches and departments of the Army. A clause in the Warrant, however, specially reserved to the officers of departments not having honorary rank all the rights, privileges, and advantages which they had previously enjoyed, and thus, so far as they were concerned, it was simply the abolition of the term "relative rank." The change, however, created dissatisfaction, it having been alleged that by the terms of the Warrant medical officers were deprived of their status in the Army. This was emphatically denied by the Secretary of State for War, both in the House of Commons and to a deputation of the British Medical Association, but apparently without the effect of allaying the agitation. At the meeting of the Association in August the question was raised by a report of their Parliamentary Bills Committee, when Sir T. CRAWFORD, the Director-General, protested against the course taken by that committee, and brought forward such facts in support of his views as induced the Association to refer the report back to the committee for reconsideration. We have not yet seen any statement of the result of this reference. With a view to remove any doubt which might still remain on the subject, and to ensure the full advantages of their rank to the medical officers beyond the possibility of cavil, Mr. STANHOPE decided that in future, whenever a medical officer is gazetted on appointment or promotion, his corresponding military rank shall be announced together with his departmental. Owing to the reductions in the force employed in Egypt, there was no examination for admission into the Army Medical Department in August, and it is announced that there will be none in February. The Royal Navy and Indian Medical Services had an abundant supply of candidates. While there has been nothing requiring special note as regards these services, with the exception already stated, we regret to find that no steps have been taken to remove the real grievances under which the Army and Indian services suffer. Of these, we pointed in our last *annus medicus* to the injustice done to the Army surgeons, in their commissions bearing date four months later than those of the Indian and Naval surgeons who pass their competitive examinations at the same time; to the brigade-surgeons in India, in their being, though nominally recognised, denied the advantages of pay and allowances which ought in justice to attach to their rank; and to the service generally, in the recommendations for rewards being almost exclusively in the hands of the naval and military officers, while the heads of the Medical Departments are practically ignored and their recommendations too often set aside. These are points which should be urged on the attention of the Government, instead of sentimental questions of military titles and designations. In this connexion we may call attention to a suggestive article by our correspondent published in our present issue.

The Medical Council.

The history of the Medical Council for the year has been noticeable. The Council met three times; in February for eight days, in May for ten days, and in November for five days. The Council was the new Council as constituted by the Act of 1886, including five direct representatives of the profession, and separate representatives of the Scottish universities hitherto represented conjointly. The chief features of the February meeting were the opening address of the President, reviewing eloquently the progress of medicine and of legislation affecting medicine in the Victorian era—characterised by the grace of Sir HENRY ACLAND'S thought and that rare combination of reverence for the great ones of the past with a hopeful but slightly misgiving feeling towards the more numerous masters of the future; the action of the Council—unsuccessful, but none the less creditable—in resolving to ask the powerful medical corporations of England and Ireland respectively to admit the Apothecaries into their scheme of licensing examinations; the passing of several resolutions defining the scheme of the Council for appointing inspectors of examinations under the Act; the recognition for purposes of registration of certain diplomas in Sanitary Science, Public Health, and State Medicine, as provided for in the new Act; and the unanimous acceptance of a motion by Dr. GLOVER for a committee to consider the best means of increasing the practical element in medical education. Sir HENRY ACLAND, at the time of this session of the Council, had the honour of entertaining the Premier, Lord SALISBURY, and other distinguished guests, at a breakfast given to the Council. He expressed an intention of reluctantly retiring from the Council at this meeting, in accordance with the advice of medical friends, but was prevailed on to continue at his post till the May meeting. At this meeting he did retire, after serving the Council from its beginning, and having filled the chair with great ability and devotion for thirteen years. He was replaced with the unanimous vote of the Council by Mr. MARSHALL. Sir HENRY ACLAND received the warmest thanks of the Council for his long service, and a committee was appointed to draw up a suitable address. His last act in the Council was to propose a loyal address of congratulation to Her Majesty on her Jubilee year, in which the blessings of her reign were happily set forth. He had the disappointment of having to announce the failure of his efforts to induce the Colleges of England and Ireland o take the Apothecaries into their scheme. After this an attempt was made in the Council to struggle the Apothecaries by refusing to appoint surgical examiners. But this did not succeed, the Council believing that the Legislature, by the Act of 1886, intended the Apothecaries to have a further lease of function. Accordingly it appointed surgical examiners for the Apothecaries in both England and Ireland. One great feature of the May meeting of the Council was the discussion of schemes of devolution. Two Standing Committees were appointed: one the Education Committee, and the other the Examinations Committee. Besides this, the Executive Committee was enlarged by an additional member for Scotland and for Ireland, and it was charged to exercise the powers and duties of the Council, with certain defined limitations, as to [illegible]

Digitized by Google

necessary or expedient. By these measures it is hoped that subjects will be digested and prepared for the consideration of a Council otherwise too large and heterogeneous for the quick and business-like discharge of its functions. At this meeting three Inspectors of examinations were appointed, with instructions to give special attention to the quality of the practical examinations. These gentlemen were—in *Medicine*, DAVID W. FINLAY, M.D. Glas., Assistant Physician at Middlesex Hospital; in *Surgery*, E. H. BENNETT, M.D. T.C.D., Professor of Surgery in Trinity College, Dublin; and in *Midwifery*, A. H. F. BARBOUR, M.D. Edin., Secretary to the Obstetrical Society of Edinburgh. The chief work of the Council at its meeting in November was of a judicial character, issuing in the removal of several names from the Medical and one from the Dental Register. At the meeting in November Sir JOHN SIMON was unfortunately absent on account of indifferent health. The honour of K.C.B. conferred by Her Majesty on this gentleman in no degree exceeds that in which he is held by the profession at home and abroad.

Medical Education.

One of the most important movements in medical education in recent times has been determined on during the past year. After a long period of incubation the Committee of Delegates of the Royal Colleges of Physicians of London and of Surgeons of England have agreed on the terms in which they would ask for a new Charter to enable the Royal Colleges to confer degrees in Medicine and Surgery on all who pass an examination under the Conjoint Examining Board of these Colleges. The question as to whether this shall be the existing examination for the conjoint Licentiateship and Membership of these Colleges, or whether additional subjects shall be added, has not yet been settled. The petition in favour and the application for a Charter were presented to the QUEEN in Council in November, and the 16th of January has been fixed for their consideration, so that all petitions for and against must be sent in to the Privy Council before that date. The object aimed at by the Royal Colleges is to remedy an injustice towards London medical students, who cannot now obtain degrees on the same terms as their competitors in Scotland and the north of England, for the severe matriculation and scientific examinations at the University of London practically prohibit most London students from obtaining a degree, in spite of a good professional training and a severely tested professional knowledge. With the exception of the Apothecaries' Society, everyone interested in the movement allows the existence of the injustice, and asks for the redress of the grievance. But objections of all kinds have been made as to the methods by which the redress is sought. The "incorporation of an equal number of Fellows of the two Royal Colleges under the name of the Senate of Physicians and Surgeons, with power to grant degrees," is strongly opposed, by those who are interested in the higher academic education in London, as forming a one-Faculty University, and as overlooking and thus probably postponing for many years, if not rendering impossible, the establishing of a full Teaching University in London with all the necessary Faculties in Arts, Science, Laws, and Medicine. It was therefore urged that the Royal Colleges should, as the representatives of the medical schools of London, combine with University and King's Colleges, as the two most important and best equipped Colleges in the metropolis, in applying for a Joint Charter on the lines of the Victoria University; but the Royal Colleges objected to combined action, plainly stating that they only sought to remove a professional grievance, and, as professional corporations, were not called on to express an opinion on the question of higher educational requirements in London. No other course then remained for the two teaching Colleges (King's and University) but to apply for a Charter to form a University, of which they would at first constitute the Faculties of Arts, Laws, and Science, and, conjointly with every other medical school in London which was to be duly represented on the Governing Board, that of Medicine. Petitions in support were drawn up by the Councils of these Colleges, and were laid before the Privy Council in July. This action alarmed the authorities of the existing University, who naturally object to the large London Colleges following the example of Owens College, and affirming their belief in the superior advantages of training in a thorough curriculum to even the highest examination results. It could hardly have been expected from the history of University College that all its supporters would approve of the new departure. Lord KIMBERLEY, the President of the Council, and some other members closely identified with the University of London, gave up their seats on the Council; but the vacancies were at once filled; Mr. ERICHSEN was elected president of the new body, and King's and University Colleges are now in complete harmony on the scheme. A petition objecting to a Charter which will exclude their examinees from obtaining degrees, without going through the ordeal of, and paying the fees for, the Conjoint Examining Board of the Royal Colleges, has also been lodged by the Apothecaries' Society; and this action is supported by the Association of General Practitioners, who point out that exclusion of the Apothecaries, and the absence of representation of the general practitioners of England on a Senate practically made up of the two Councils of the Royal Colleges, constitute in their opinion omissions fatal to the scheme, which otherwise they would support. The Scotch and Irish Colleges of Physicians and Surgeons ask for similar powers should any be conferred on the English bodies. The provincial schools also urge that the new legislation should not be confined to metropolitan students, especially if the Royal Colleges are to become the degree-granting body, as they consider that these bodies exist for the provincial schools as well as for the metropolis, and therefore the students from both should receive from them identical treatment in every respect. Under all these circumstances, and with such conflicting interests—some general and some purely selfish,—a strong Royal Commission, as we urged in the summer, must clearly be appointed to hear the petitioners, weigh evidence, and report. This will take time, but delay in this matter will be much less disastrous than any precipitate and one-sided action. Among other University matters we must mention the incorporation of the Yorkshire College at Leeds with the Victoria University, and that the scheme of internal reform of the University of London, the joint outcome of the deliberations of the Committees of Convocation pre-

Digitized by Google

sided over by Lord Justice FRY and Sir P. MAGNUS, and of the Senate, though long promised, has not yet been put before Convocation, and it does not seem likely that it will see the light at present.

The Medical Societies.

The only change that we can suggest towards enhancing the general usefulness of our Medical Societies is an increase in the number of communications on therapeutical subjects. The Clinical meetings of the Medical Society of London have proved a great success, because of the actual exhibition and demonstration of living specimens of disease; we have always advocated their extension, and, thanks to the energy of Dr. SAMUEL WEST and Mr. BERNARD PITTS, the oldest Medical Society may be congratulated on the success of the revival. The most important or interesting papers which have appeared at the Societies during the past year may be here enumerated:—Mr. BLAND SUTTON on Suture of Divided Nerves; Dr. RALFE on Phosphatic Diabetes; Mr. PEARCE GOULD on Wound of Common Femoral Vein; Surgical Treatment of Hydatids of the Liver, by Mr. BARWELL, Dr. COUPLAND, and Mr. OWEN; Preventive Inoculations, by Dr. WILLOUGHBY; the Lettsomian Lectures on some of the Mental Affections of Childhood and Youth, by Dr. LANGDON DOWN; Pathology of Colles' Fracture, by Mr. D'ARCY POWER Multiple Perforative Necrosis of Skull of Tubercular Origin, by Mr. BILTON POLLARD; Nephro-lithotomy and Renal Surgery, by Mr. HENRY MORRIS, Mr. HOWARD MARSH, and Mr. W. H. BENNETT—papers which provoked a good discussion; Exostoses of Skull with Atrophy of Optic Nerves, by Mr. NETTLESHIP; Cases of Acute Cerebral Disease with Ocular Symptoms, by Mr. G. A. BERRY; Primary Nerve Suture, by Mr. ROWE; Tremor and Incipient Graves' Disease, by Dr. DYSON; Rare Aneurysm of Undefended Space, by Dr. ANGEL MONEY; Graves' Disease, by Mr. SNELL; Removal of both Superior Maxillæ, by Dr. LEOPOLD SERVAIS; Conservative Surgery in Diseases of Foot and Ankle, by Dr. WHEELER; Rupture of Urinary Bladder, by Mr. HENRY MORRIS; Shedding of Teeth in Tabes Dorsalis, by Dr. HALE WHITE; Endothelioma of Dura Mater, by Dr. HYLA GREVES; Mr. SHATTOCK on Ectopia Vesicæ; Mr. CLUTTON on Retro-pharyngeal Abscess; Epilepsy following an Injury to the Leg, by Dr. HADDEN; Diseases of Hip Joint in Children, by Mr. G. A. WRIGHT; Conjugate Palsy of Ocular Muscles and Nystagmus, by Dr. GOWERS; Mechanism of the Third Stage of Labour, by Dr. CHAMPNEYS; Changes in the Spinal Cord and Peripheral Nerves after Amputation, by Dr. E. S. REYNOLDS; Contraction of Metatarso-phalangeal Joint of Great Toe, by Mr. DAVIES-COLLEY; Hereditary Tremors, by Dr. S. WEST; Mr. ATKIN on Supra-pubic Suppuration; Psoriasis, Pityriasis and Rheumatism, by Sir DYCE DUCKWORTH; the Marsupial Heart, by Dr. CUNNINGHAM; Stellwag's Symptom, by Mr. WHERRY; Hypertrophic Goitre, with Secondary Tumours in the Skull, by Dr. COATS; Congenital Dislocation of Hip, by Mr. BOWLBY; Development of Hip Joint, by Mr. LOCKWOOD; Writer's Cramp, by Dr. POORE; Omental Lipoma treated by Abdominal Section, by Mr. MEREDITH; Abdominal Exploration for Chronic Intestinal Obstruction by Mr. BERNARD PITTS; Resection of Pylorus, by Mr. M'ARDLE; Œsophagotomy for Removal of Foreign Bodies, by Mr. BARTON; Double Ophthalmoplegia, by Dr. THOMAS; Enterorraphy, by Mr. BARKER and Mr. S. BISHOP; Fallopian Tube Diseases, by Mr. LAWSON TAIT and Dr. LEWERS; Artificial Globes, by Dr. MULES and Mr. LANG; Sarcoma of Recto-vesical Fascia, by Mr. LEOPOLD HUDSON; Cultivation Experiments with New Growths, by Mr. BALLANCE and Mr. SHATTOCK; Headache and Uric Acid Excretion, by Dr. HAIG; Latent Typhoid Fever and Cardiac Thrombosis, by Dr. MONTGOMERY; Ruptured Brachial Plexus, by Mr. MORRISON; Tubo-ovarian Cysts, by Dr. W. S. A. GRIFFITH; Uni-ocular Optic Atrophy and Temporal Hemianopsia, by Mr. STORY; Choroido-retinitis, by Dr. BRAILEY; Hereditary Optic Atrophy, by Dr. S. H. HABERSHON; Experimental Hæmorrhage Infarction of Liver, by Dr. WOOLDRIDGE; Fœtus with Spina Bifida Occulta, by Mr. BLAND SUTTON; Simple Stricture of Bile Duct, by Dr. SIDNEY PHILLIPS; Peritoneal Surgery, by Mr. BARWELL, Mr. LAWFORD KNAGGS, Mr. T. KILNER CLARKE and Mr. FREDERICK TREVES; Mode of Fixation of Scapula, by Mr. ARBUTHNOT LANE; the Presystolic Murmur, by Dr. BRISTOWE; Ulcerative Endocarditis, with Congenital Malformation of Heart, by Dr. SUCKLING; Cystic Tumours, by Dr. CHARLEWOOD TURNER; Supra-pubic Drainage, by Sir HENRY THOMPSON; Mr. M'GILL on Prostatectomy; Brain Disease with Hemianopia, by Dr. SHARKEY; Cholecystotomy, by Mr. KNOWSLEY THORNTON; Rupture of Trachea, by Mr. GARRARD; Acute Enlargement of Thyroid Gland in a Child, by Dr. THOMAS BARLOW; Acute Pneumoparesis, by Dr. B. W. RICHARDSON; Hereditary Defect of Ocular Movements, by Mr. LAWFORD; Eclampsia of Pregnancy, by Dr. HERMAN; and last, but by no means least, Professor CROOKSHANK's investigation into the so-called Hendon Cow Disease, and its relation to Scarlet Fever of Man.

Medical Congresses, &c.

The ninth International Medical Congress met at Washington, United States, on Sept. 5th, under the presidency of Dr. NATHAN SMITH DAVIS, M.D., LL.D. The President of the United States, Mr. CLEVELAND, graced the occasion with his presence, as did also Mr. BAYARD, Secretary of State. The Address in Medicine was delivered by Dr. DAVIS, and we had the pleasure of publishing it in full the same week. An important address on the Causes, Mechanism, and Rational Treatment of Fever was delivered by Dr. AUSTIN FLINT, whose late honoured father had been appointed to the presidency, and whose absence was so conspicuous. There were 2600 members and about 300 foreigners, representing all European countries. Our own country was well represented. The success of the Congress, in spite of adverse circumstances and prognostications, is a matter for congratulation.

We must not omit notice of a singularly successful meeting at Vienna—the Sixth International Congress of Hygiene. It was opened in a very appropriate and earnest speech by the Crown Prince RUDOLF, and attended by no less than 2400 members, amongst whom were distinguished representatives of sanitary medicine in England—which, by the way, was much honoured by many of the leading foreign speakers, notably by PETTENKOFER. Amongst our countrymen present were Sir SPENCER WELLS, Sir DOUGLAS GALTON, Dr. CAMERON, M.P., Professor HUMPHRY, Pro-

Digitized by Google

fessor FRANKLAND, Professor CORFIELD, Dr. C. E. RICKARD (Birmingham), Dr. RUSSELL (Glasgow), and Mr. SHIRLEY MURPHY.

The Sanitary Institute of Great Britain met at Bolton under the presidency of Lord BASING. A very suggestive address was delivered by Dr. J. RUSSELL REYNOLDS on Sanitary Science and Practical Medicine. The progress of sanitary work in the provinces was illustrated by a paper read by Mr. SERGEANT, medical officer of health for Bolton, in which the notification of infectious diseases was much insisted on.

The British Medical Association had a very successful meeting in Dublin, under the genial and able presidency of Dr. BANKS. Dr. GAIRDNER of Glasgow delivered the Address on Medicine, and with much force and dignity showed that medicine had advanced greatly since HIPPOCRATES, in spite of Sir WILLIAM HAMILTON'S unbelieving question on the subject. The Address in Surgery was by Dr. HAMILTON, and had reference chiefly to the Antiseptic doctrine, the value of which he fully admitted. Sir THOMAS CRAWFORD, the head of the Medical Department, contributed much to the interest of the proceedings by a lively and successful attack on the action of the Parliamentary Committee in regard to its Report on the question of Relative Rank and the consequences to Medical Officers of the Army. Sir THOMAS also carried a resolution directing attention to the monopoly of some hospital appointments by the holders of certain English corporations as inconsistent with the spirit of the age and of the Medical Act. Amongst distinguished foreigners present was Dr. APOSTOLI of Paris, who explained his electrical treatment of fibroids, and gave illustrations.

Forensic Medicine.

During the year just terminating a number of cases of deep forensic interest have been recorded in these columns. The most sensational may be grouped under two heads—criminal abortion and poisoning. Of the former class no less than five cases were investigated by the coroner for Central Middlesex. Two of these occurred in married and three in single women. In four of them the pregnancy had been terminated by gross mechanical injury. In three the instrumentation was practised by a second person. In one there were two vaginal punctures, seemingly self-inflicted. In the fifth case the evidence was not clear as to the precise means adopted to bring on abortion. In only one of these cases was a conviction obtained—namely, that of a single woman aged twenty-two. It will be remembered that BAXTER, an unqualified medical man, and POTTS, a nurse, acting in collusion, inflicted violent instrumental injuries upon the deceased. They were tried at the Central Criminal Court, convicted, and sentenced each to fifteen years' penal servitude. The above record of cases brought to light may be taken as indicating that the crime of illegally procuring abortion is a very common one. Probably, in the majority of instances the victims escape with their lives, or, if they die, the death is attributed to natural causes. It behoves medical men, when called to cases of recent miscarriage, to be on the alert, and with discriminating inquiry look for manifestations of guilty practice. Amongst the numerous cases of poisoning two stand out in prominent relief. In each the tragic act was homicidal and marked by features of unnatural cruelty. In the Toxteth Park case a workhouse nurse was proved to have murdered her daughter, aged eleven, her apparent motive having been the obtaining of a paltry sum of money for which the life of the child was insured. The means adopted to effect the woman's guilty purpose was the administration of a corrosive poison, probably sulphuric acid. The convict was sentenced to death and hanged. The second case was fully reported in our last number. A retired surgeon-major named CROSS compassed the death of his wife by arsenical poison. The motive seems to have been the desire to possess himself of a woman with whom he had previously carried on illicit intercourse. The unhappy murderer now lies under sentence of death. We have recorded two instances of poisoning by oxalic acid. A woman aged forty-five, suffering from meningeal gumma, ended her life by taking a huge dose of the acid, which proved rapidly fatal. In the second case, as we pointed out at the time, the verdict of the coroner's jury seemed strangely inconsistent with the medical evidence; although there seemed the clearest proof that the death was suicidal, the jury ignored this in their finding. It seems to us that the law regarding the sale of poisons is wofully lax in reference to oxalic acid, since there is no difficulty in purchasing more than fatal quantities. An unfortunate mishap occurred in the death of GEORGE JAMES, aged forty-seven, who rapidly succumbed after the medical administration of a dose consisting of half a drachm each of chloral hydrate and bromide of potassium. In this case the jury returned the antiquated and unscientific verdict of "Death by the visitation of God." No chloral was detected at the post-mortem, and we took occasion to note that failure of its recognition must not be taken as proof that it had not been exhibited. Of lead poisoning not a few examples have been demonstrated. The most notable was the case of MATILDA MORGAN, aged thirty-eight, a white-lead worker, who died from coma following saturnine delirium. Mr. WYNTER BLYTH has made some interesting analyses of the viscera of persons who have died from the effects of lead. This authority detected the metal in the brain, liver, and kidneys. He supported the reasonable hypothesis that the grave saturnine cerebral symptoms so frequently manifested may be explained by assuming that the lead, entering into a combination with the structural nerve elements, prevented or annulled their function. An epidemic of lead poisoning occurred at Villemontais, St. Maurice. The lead was derived from stones used for grinding corn. In another instance some plum jam became impregnated with lead by absorption of the glazing material of preserving pans. We need only make passing mention of the death of MIRIAM ANGEL, murdered by ISRAEL LIPSKI, who expiated his guilt on the scaffold. The murderer first resorted to mechanical violence, and completed his atrocious crime by pouring nitric acid down the throat of his victim. At the Guildford Assizes a medical man was sued for damages for alleged neglect whilst attending a woman in confinement. He was accused of contributing to rupture of the perineum and of subsequent want of attention. Rightly, as we think, the verdict was given for the defendant. There are two points of interest relating to procedure in the Coroner's Court worthy of comment.

Digitized by Google

Ipswich Mr. VULLIAMY decided to hear a case with closed doors. The decision met with violent objection from the press and jury, but the legality of the coroner's action was upheld by the Lord Chancellor, At a subsequent meeting of the Court a member of the press was committed for contempt of Court for openly advising the jury not to acquiesce in the coroner's ruling. A writ of *habeas corpus* was obtained from Mr. Justice DAY. The matter, however, did not proceed to trial, for the person committed was liberated after making apology. An Act has been passed to consolidate the laws pertaining to the jurisdiction of coroners. Amendment of the law is promised for a future session of Parliament. We would commend the interest and action taken by the Manchester Medico-Ethical Association for the reform of the procedure in Coroners' Courts. Finally, we may mention three cases illustrating the value of a complete post-mortem examination, in each of which poisoning was suspected, but in none substantiated. In the first case, there was perforating ulcer of the stomach, in the second, ulcerative perforation of the gall bladder, and in the third, mechanical obstruction of the bowels. Finally, in connexion with the subject of Forensic Medicine, we would call attention to the excellent post-graduate course of lectures by Mr. PEPPER, published in our columns in August, September, and November of the present year.

Public Health.

A general review of the health of England and Wales during that portion of 1887 for which accurate statistics are available goes to show that, apart from certain local prevalences of disease, the year has been a healthy one. During each of the first three quarters the death-rate from all causes was below the average annual rate for the preceding ten years, and apart from the third quarter, when there was an almost infinitesimal rise in the zymotic rate, that rate was also below the average. Of the diseases included in the zymotic group, diarrhœa was the one which caused the most striking increase, the death-rate per 1000 during the third quarter being 2·06, as against an average of 1·83, the rainfall being 1·44 inch below the average amount in the corresponding periods of seventy-two years, and the mean temperature being 0·9° above the average for the corresponding periods of 116 years. The "fever" death-rate was throughout below the average; indeed, as regards the second quarter, there has, since quarterly returns have been published, only once been a lower rate. During the fourth quarter of the year the most striking occurrences have been localised prevalences of scarlet fever and of small-pox, which have severely tried sanitary authorities in respect of measures of isolation. During the first three quarters the scarlet fever rate remained steadily below the average, but towards the close of the third period there were certain marked epidemics, especially in the sub-districts of Glossop, Todmorden, Sowerby, and Milford. In the metropolis the disease extended widely during the month of October, although for many weeks the number of deaths remained below the corrected average, and it became a question how far this was due to mere mildness of the epidemic, or to the increasing number of persons who voluntarily sought isolation and treatment in the hospitals of the Metropolitan Asylums Board. So far as cases were concerned, the height of the epidemic was reached about the middle of November, when 2600 cases were under treatment in the hospitals of the Asylums Board, in addition to 164 in the London Fever Hospital. The fatal attacks reached their highest point in the week ending Nov. 5th, when sixty-nine deaths were registered; but this number only exceeded the corrected average by eight. This epidemic, by no means yet concluded, will be mainly remembered by reason of the evidence it has afforded of the need for such action on the lines recommended by the Royal Commission on Small-pox and Fever Hospitals towards a reconstitution of the Metropolitan Asylums Board as will make that body a true representative of the sanitary interests of the metropolis. As to small-pox, that disease, whilst showing some general tendency to spread, has mainly appeared as an epidemic in and around Sheffield, Leeds, and Bristol, and in most of the places where it has occurred it has found sanitary authorities most imperfectly provided with the means of isolation special to the needs of that infection. Increasing attention has during the year been called to the fact that small-pox hospitals, if established at all, must be ready in advance; and that, in the case of urban, if not rural, communities, they ought to be so contrived as to secure the destruction within their own walls of all matters calculated to spread the infection beyond their area. Amongst the more important investigations into matters relating to public health that have been made during the year, we may mention the continuance of the Wimbledon scarlatina outbreak into January and February, and the circumstance that this prevalence was stated to have such relations to milk and to cow disease as practically to bring it within the same category as the now well-remembered Hendon case, which has been so much discussed during the present year in official papers, and at some of the Medical Societies. Diphtheria, too, has been the subject of repeated inquiry by local health officers and officers of the central authority; and although the views expressed by Dr. GEORGE TURNER in his report to the Local Government Board as to the relation of the human disease to certain allied affections in the lower animals can only be regarded as provisional, in so far as their acceptance is concerned, yet they are well worthy of being made the basis of further work in the same direction. At Ealing an important diphtheria prevalence occurred early in the year, but the facilities for the investigation of its causes were not such as to enable any satisfactory solution to be arrived at. The sanitary state of Margate, in reference to the relation in that place of enteric fever to the grave sanitary defects which were discovered, has been more than once discussed by us, and we are glad to say that there are now grounds for believing that the Corporation of that place have determined that their attractive town shall no longer be subject to the stigma which attaches to it. Of [illegible] the temporary damage to the borough which has resulted from the inquiry that was held will be more than compensated for. Amongst incidental matters relating to health, we would advert to the exhaustive [illegible] report by General SCOTT and Mr. W. H. POWELL [illegible] the East London Water Company's [illegible] reference to the presence of [illegible] how the fish had had access to the [illegible] interesting points relating to the [illegible]

Digitized by Google

female gravid eel and of young eelets were discussed; and assuming that the views of the reporters was correct, the remedy to be applied is of the simplest character. During the year the question of the need for open space about human dwellings has also been very prominently brought forward, especially in the case of Oxford. There is unquestioned difficulty in dealing with the re-erection of buildings in old and crowded towns, but this difficulty ought to be got over without sacrificing the health interests of the public altogether to those of owners whose property has acquired a value apart from any special expenditure of their own; and we hope that sanitary authorities will in this matter remember that they are guardians of the public health, and that they must not transmit to their descendants difficulties that can only increase in intensity the longer a remedy is deferred. Cholera has fortunately once again been marked by its absence from our shores during another year of the European epidemic of 1884–87. It has engaged much attention at home, and, as we recently explained in dealing with its history, the past epidemic has only gone to strengthen the position which we have taken up in this country as to the futility of quarantine measures and the overwhelming importance of sanitation as a preventive of the disease. At the last moment news reaches us to the effect that official inquiries which are being made in Italy will probably, once for all, lead to the adoption in that country of a system of medical inspection largely resembling that which has so well served England, and which has had the indirect advantage of educating the public to trust for the prevention of both cholera and other preventable diseases in an improvement of the sanitary conditions by which they are surrounded.

Hospital Mirror.

During the past year in the Mirror of Hospital Practice numerous cases have been brought forward, chiefly from the more general departments of medical work, illustrative of rare diseases, diseases attended by unusual symptoms or the presence of unusual complications, new or uncommon modes of treatment either operative or medicinal, or cases of special pathological interest. Although the majority of these have been obtained from the hospitals of the United Kingdom, several have been forwarded from the colonies and British dependencies. A short summary of the more important will include the following:—A case of general tuberculosis following (? tubercular) disease of the great toe joint after injury; another of the same disease in a patient who had received extensive fractures of the skull and bones of the face three years previously; an example of Addison's disease; a fatal case of hydrophobia, the incubation period of which was apparently two years, and in which great temporary relief was obtained by the use of ether spray to the back of the neck; seven successive cases of charbon successfully treated by excision; tetanus, in which recovery followed the excision of the cicatrix and surrounding parts five weeks after the infliction of the wound; recovery after an attack of acute meningitis, and in another instance after acute cerebro-spinal meningitis, of which also a fatal case is recorded; cerebral embolism and hæmorrhage into the lateral ventricle after parturition; cerebral abscess in which trephining was unsuccessful; cerebellar abscess with obscure history; extensive diphtheritic paralysis, from which the patient recovered; early pseudo-hypertrophic paralysis; general paralysis of the insane; and cases of paraplegia; the successful treatment of empyema after long duration of the disease, and cases instancing the usefulness of intubation of the larynx. Of the diseases of the circulatory system: cardiac hypertrophy; ulcerative endocarditis; multiple aneurysms of the aorta; death after rupture of an aneurysm of the coronary artery; ligature of the external iliac for high femoral aneurysm; for inguinal aneurysm in a patient who had had a left popliteal aneurysm cured by compression of the femoral and the introduction of needles into the sac a few months previously; aneurysm of the superficial femoral in Hunter's canal, preceded by aneurysm of the common femoral of the opposite limb, both treated by ligature; compression for popliteal aneurysm; amputation of the limb for diffused aneurysm of the anterior tibial artery, also for rupture of the popliteal vessels; and ligature of the brachial for secondary hæmorrhage. It is in connexion with the digestive system that the greatest activity has been shown so far as regards the records of treatment and disease in this department of THE LANCET; and this has been especially marked in the treatment of hernia, whether strangulated or in a condition calling for radical cure. Here there are examples of suppurative gastritis; perforating ulcer of the stomach; perforation of a latent ulcer of the intestine after a fall; perforation of the gall-bladder by an ulcer due to the presence of a small gall-stone in a girl aged twenty-three; a rare case of vomiting of gall-stones; the treatment of hepatic abscess; incision and resection of a portion of rib for hydatid of the liver; three cases of non-tropical dysentery occurring at one hospital; a fatal case of intussusception (with suggestions as to the employment of abdominal section at an earlier period on the failure of air injections); three cases of acute internal strangulation by a band—one rapidly fatal; another due to a similar condition, in which the patient recovered after abdominal section and a later performance of enterectomy; a diaphragmatic hernia was found in the third, but the condition of the patient during life did not permit of operative interference. Of the major operations may be mentioned four instances of gastrostomy for malignant disease of the œsophagus, life in one case being prolonged for four months. In another the result is unknown; the patient was alive some months afterwards. The operation of pylorectomy for carcinoma of the stomach is recorded, a successful cholecystotomy for gall-stones, and colotomy in a case of scirrhus of the pancreas. We have recorded herniotomy in inguinal, femoral, and umbilical hernia when strangulated, usually combined with the radical cure, including the removal of the testis in two cases of inguinal hernia; also examples of the present method of operation when the hernia is not strangulated, and when trusses are unsuccessful in keeping the rupture in check. In a case of partial enterocele the intestine sloughed, and a fæcal fistula, which closed without operation, resulted. In one of the congenital variety, where operation was performed for strangulation seven days after its last descent, ulceration was found to have occurred, and this healed after immediate suturing by LEMBERT'S method. In a man, aged forty-eight, at

Digitized by Google

operation five days after symptoms of strangulation, gangrenous intestine was found in the sac and left *in situ* after incision, and the resulting fæcal fistula was closed by resection about two months later. There is one record of a rupture of the rectum. As during the year 1886, there are numerous recorded cases of operation on the urinary bladder, especially by the supra-pubic method, both for calculus and tumour in the male, and in the female removal of vesical growths by the urethra and after vaginal cystotomy; in the latter the history of the disease is given for some years, and the change in the character of the growth noted after three operations. Death after the performance of external urethrotomy; traumatic stricture in a child of three; the treatment of urinary fistulæ; retention before apoplectic attacks; and a most important case of intra-peritoneal rupture of the urinary bladder, treated by perineal incision and suturing of the rent after abdominal section, which proved fatal through hæmorrhage from the perineum. A series of cases illustrative of the surgical treatment of diseases and injuries of the kidneys, including nephrotomy, nephrectomy, and nephro-lithotomy. Operations on the pelvic organs: supra-vaginal hysterectomy; and abdominal section for hæmato-salpinx, hydro-salpinx, ovaritis, ovarian dysmenorrhœa, parovarian cyst, and the removal of ovarian tumours, in one case from a patient aged thirteen, have been recorded, as well as one on excision of the thyroid gland, and the cure of its hypertrophy by injection of iodine. Also cases of parturition after amputation of the cervix, in other instances the complication of cervical emphysema or hemiplegia; acute suppurative osteomyelitis of the humerus; fatal necrosis of the lower jaw, and removal of the coccyx for coccydynia; disease of the elbow and ankle, the treatment of an unusual complication after excision of the hip, loose cartilages in the knee joint, and multiple synovial cysts around it; also, recently, cases in which the knee joint was secondarily involved and the joint successfully drained. Operation for deformity after disease of the knee, and successful operation for cleft palate in children of twelve months old. The discovery and localisation of a metallic body by means of a special induction balance and its subsequent removal; recovery after bullet wound of lung, and after penetrating wounds of the abdomen, with protrusion of intestine. Compound fractures of the skull have been frequently recorded, and the success of the antiseptic treatment fully shown in the large percentage of recoveries after severe injury or operation, either for removal of depressed fragments or for the relief of symptoms such as paralysis of the arm, spasm of the muscles of the face and arm, or for high temperature. Recovery after forcible extension for fracture of the spine; prolongation of life for ten months in a case of fracture of the fifth cervical; extensive fracture of the pelvic bones. Fractures of the femur: simple, with rupture of artery and vein; compound, in which amputation was performed and secondary hæmorrhage from the artery took place; also compound fractures into joints. Dislocations of the humerus (post-acromial and subspinous): of elbow, with wound of ulnar nerve; of hip in a child of five; of knee, ankle, astragalus, carpus, and metatarsus. In addition to the new growths of the bladder, a rare form of scirrhus of the breast; scirrhus of the pancreas; epithelial tumours of the tongue and glands, soft palate, lower jaw, and generative organs. Some operations for disease in the region of the neck and mouth called for exceptional skill and boldness, as most important structures were involved, and in one a special feature in the after treatment calls for notice. Sarcoma of the tongue, antrum, ear, knee, foot, femur, thigh, scapula (in one instance the scapula and upper extremity were removed), and secondary growths of the lungs. We must specially mention a series of these growths, as the life history was fully recorded.

"The Lancet" Sanitary Commissions and Special Articles.

THE immunity from cholera enjoyed by England at a time when other countries were suffering severely from this disease has been matter for much congratulation, but the work of THE LANCET Sanitary Commission has shown that there is still serious sanitary neglect in some districts, especially in those which are exposed to cholera introduced by the Thames. The city of Rochester, which was selected for inquiry, afforded considerable evidence that local authorities were not all inspired by the same desire for the preservation of the health of those dependent upon them. Rochester, indeed, had neglected to perform one of the primary sanitary duties—the provision of an efficient system for the removal of excremental refuse. The city is entirely dependent upon the use of cesspools, except that a few house drains are connected with those intended for storm water only. The abominable nuisance created by these cesspools was apparent at the time of our Commissioner's visit, and the inhabitants loudly complained of the offensive odours which surrounded them and freely entered their houses. Perhaps the most striking instance to which reference was made in the report was that of a house in which the wainscoating had given way, and which afforded direct communication between the cesspool and the house, swarms of flies entering the dwelling-room from the cesspool. In many of the courts the open cesspools were said to be most offensive in summer, and the inquiry left no doubt that the Rochester authority were incurring a serious responsibility in not adopting some better system than that in existence. Even in the emptying of these receptacles the townspeople receive no assistance from those who are appointed to protect their interests. This duty is undertaken by scavengers, with whom householders have themselves to arrange, and often the filth has to be carried through the houses on its way from the cesspool to the cart. Again, in regard to the condition of dwelling-houses occupied by poor persons there was the same negligence. Houses were found damp and unfit for occupation, with floors broken and window-sashes perished. Rochester had, thanks to the enterprise of public companies, a good water supply, and the local authority had by providing a hospital shown its desire to limit the prevalence of infectious disease, but in the respects to which we have referred seriously neglected to perform its duty. The water supply for the metropolis also engaged the attention of our Commissioners, who carefully inspected the river Thames from Hampton Court to Staines. The inspection showed that London water supplies derived from this river are liable to pollution from many sources, especially from cesspools, which are situated in increasing numbers near its banks, and the contents of

Digitized by Google

which undoubtedly pass into the water which is later used for human consumption. Chemical analysis, it was admitted, would give no sufficient indication of this pollution; but chemical analysis, our Commissioners insisted, could not be trusted to decide this question, and it was urged that London should no longer rely upon supplies which were thus liable to contamination. The increased number of house-boats, particularly at the time of the Henley Regatta, added another and grave element of danger. During the previous year we had shown that these boats, draining direct into the river, were a source of contamination. The Thames Conservancy thereupon issued a new bye-law to prevent this evil; but this reform remained in abeyance, and nothing was done. We were consequently obliged to take up the subject again, and published another report during this year's regatta. The result has been satisfactory, for the QUEEN gave her assent to the new bye-law, and this, after our denunciations, was considered so urgent that the Royal signature was obtained during Jubilee week. It is now illegal for house-boats to drain into the Thames, and we trust the new bye-law will be strictly enforced. The condition of the pit-brow women had excited much public sympathy and interest. We instituted an inquiry on the spot, and found that some very young children were employed to do heavy work; and that women also worked in all weathers without shelter. That proper shelter should be provided, the work of young persons restricted, and women prevented from lifting heavy loads during the period of gestation, seemed obviously necessary.

Among the various special articles dealing with sanitary questions, may be noted a careful description of Tangier as a health resort, dealing with the climatic advantages of this favoured spot. We also gave details concerning the sanitary measures adopted at Toulon since the cessation of the cholera epidemic, the new sewers built at Monaco, the defective drainage and ventilation of the renowned Monte Carlo Casino, together with very remarkable statistics showing the exceptional climate enjoyed at Hyères during the last six years. Quite recently we published a full account of the water supply and drainage of Venice, and some details concerning the rival port of Trieste. The great gathering of sanitary reformers who, to the number of 2400, participated in the Sixth International Congress of Hygiene, was fully described in our columns. Previously to this Congress, where questions relating to drainage were naturally often discussed, we gave the results of a special investigation made on our behalf concerning the practical working of the pail system at Manchester. The opponents of drainage by gravitation and water carriage will find in this article useful suggestions for an alternate method.

Medical Ethics.

The year now closing has witnessed an attempt, as unwise as it was necessarily impossible, to degrade the very principles of medicine themselves to the level of the quack's rule of thumb and the light studies of a school for children. Happily this project, introduced as it was with all the suitable accompaniments of light popular literature, has ended in well-merited failure. We congratulate the non-medical classes on this event, which marks the extinction of what implied for them a very serious danger. We also congratulate the medical profession, and particularly the Colleges of Physicians and Surgeons, on the firmness with which they have opposed a scheme so preposterous in itself and so prejudicial to the public good. Last, but not least, we must express our appreciation of the conduct of some of our medical brethren at first connected with this undertaking, who had the candour and decision to withdraw on discerning its true character. This movement will be remembered as a daring and undesirable venture in a new field of commercial and pseudo-medical enterprise. Its effectual suppression will sufficiently vindicate, if required, the reality of a justly scrupulous ethical principle in the medical practice of our time.

Honours to the Profession.

The honours which have fallen to the profession, so far as can they can be measured by titles and State favours, have not been adequate to the occasion. The House of Lords is still poor in the absence of men of science, and our own profession has still no representative there. That is, perhaps, worse for the House than for the profession. In any case the Jubilee year was a favourable one for a new departure, and it has not been so used. Well-deserved knighthoods have been conferred on Dr. GARROD, G. H. MACLEOD, Esq., and Dr. AITKEN. One was very rightly offered to Dr. GAIRDNER of Glasgow, but was declined. The following is a list of other honours which have been during the past twelve months conferred upon members of the medical profession:—

ORDER OF THE BATH.—Knights Commanders of the Second Class:—Military Division: Surgeon-General John Harry Ker Innes; Inspector-General of Hospitals William Mackenzie, M.D., Indian Medical Service; Inspector-General of Hospitals and Fleets James Jenkins, Royal Navy. Civil Division: John Simon, Esq., M.D., late Medical Officer, Privy Council Office; Arthur Mitchell, Esq., M.D., Commissioner in Lunacy in Scotland. Ordinary Members of the Military Division of the Third Class or Companions: Inspector-General of Hospitals and Fleets James Nicholas Dick, Royal Navy; Surgeon-General Herbert Taylor Reade, V.C., Medical Staff; Deputy Surgeon-General Jeffrey Allen Marston, M.D., Medical Staff. Ordinary Member of the Civil Division of the Third Class, or Companion: Professor W. H. Flower, British Museum.

ORDER OF ST. MICHAEL AND ST. GEORGE.—Ordinary Member of the Second Class or Knight Commander: James Alexander Grant, Esq., M.D., of Ottawa, in the Dominion of Canada. Companions: Sir Oscar Clayton; Surgeon Charles William Owen.

ORDER OF THE INDIAN EMPIRE.—Knights Commanders: Sir George Christopher Molesworth Birdwood, M.D.; Surgeon-General Benjamin Simpson, M.D. Companions: Thomas Beatson Christie, Esq., M.D.; Brigade-Surgeon Henry Elmesley Busteed.

COMPANIONS OF THE DISTINGUISHED SERVICE ORDER.—Surgeon-Major Thomas William Patterson, Medical Staff; Surgeon-Major Robert de la Cour Corbett, M.D., Medical Staff; Surgeon-Major Frederick William Wright, Indian Medical Service, Bengal; Surgeon Alfred William Frederick Street, Indian Medical Service, Bombay; Surgeon Alexander

Peers Adams, Indian Medical Service, Madras; Surgeon William Ainley Sykes, Indian Medical Service, Bengal; Fleet Surgeon Thomas D'Arcy Bromlow, M.D., Royal Navy.

Obituary.

We come to the sad part of our history. Those who do so much to abate and avert mortality in others have themselves to submit sooner or later to the enemy. The list of our obituary names will show how grievous has been his triumph in many cases. Some indeed have been translated at a fit age, and almost "more than fit." Dr. OGSTON, of Aberdeen, had been teaching medicine for more than half a century; and Dr. WALKER of Peterborough, who died at ninety-one, was descended from JOHN KNOW seven generations back, and had been "qualified" for seventy-one years. At eighty he walked by night across fen and fields to operate for hernia in a humble cottage with the light of a tallow candle. More wonderful still was the death of Dr. NEKLEWITSCH, of Loske in Poland, at the alleged age of 109, having seen a patient just a quarter of an hour before — a longevity almost paralleled by that of Mr. SYLVESTER, whose demise in his ninety-ninth year is recorded in our present number. Sir GEORGE BURROWS has at length succumbed, and his honoured history, as that of others in our record, takes us back to the days of ABERNETHY, LATHAM, and FARADAY. The death of others has been all too premature. Not a few died shortly after their graduation — as if the very process of entering the profession had been too much for them. Our obituary includes the history of a Hindu practitioner, who, to fit himself for the Indian Medical Service, came to England, took the Fellowship of the English College of Surgeons and the degree of Glasgow. The heredity of medical character has been illustrated in some of our histories, as in that of Mr. SAMUEL MOREWOOD, who held the office of dispensary doctor in Drapers-town in succession to his grandfather and father—in all for near a century. But if we dip into medical biography, with its graphic history of character and service, where shall we stop?—with a list that includes Mr. RICHARD QUAIN (whose munificent bequest to University College should not be allowed to pass unmentioned in this retrospect), WILSON FOX, W. F. TEEVAN, FRANCIS OGSTON, the two FERGUSES, R. E. CARRINGTON, ALFRED WILTSHIRE, JOHN BRADY, M.P., Dr. GREENHALGH, GUSTAVUS CHARLES PHILIP MURRAY, Dr. RUTHERFORD HALDANE, Dr. HENRY KENNEDY, Dr. LAUCHLAN AITKEN, Dr. CUMING of Armagh, JAMES THOMAS CARTER of Glasgow, Dr. ALEXANDER GORDON of Belfast, Dr. HENRY MILNE of Banff, Sir WILLIAM SMART, Dr. EVAN EVANS, who in 1842 made himself Apothecary, and in 1853 took the M.B. of London, CHARLES ROBERT THOMPSON of Westerham, and others. We must desist. The Science of Medicine is big with promise. With every wish that those who profess it may experience a higher appreciation at the hands of the public and of fellow-workers in other realms of duty, we go forward to another time, in the spirit of the faithful ones whose names would rebuke us if we did work slightly or unfaithfully.

DR. PROSSER JAMES has been unanimously elected a Corresponding Member of the Société d'Hygiène Française.

Annotations.

"Ne quid nimis."

DEGREES FOR LONDON MEDICAL STUDENTS.

THE different bodies interested in this question are preparing to support or oppose the application of the Royal Colleges which will be under consideration by the Privy Council after the 16th prox. We have still to refer to the petitions submitted by the Apothecaries' Society and by the Association of General Practitioners. The first-named petition, we regret to see, has committed the Society to the opinion "that no new university for the conferring of degrees in Medicine and Surgery is required in London, as the University of London already *satisfactorily and fully* performs all the functions of such a university." It has been shown over and over again in our columns that the University of London does not meet the wants and requirements of the London students, and it is because it has no concern except with the picked men that the present agitation has arisen. We had hoped that the Society would have had some sympathy for the just claims of students in London, independently of the question whether they became future licentiates of the Hall, or might obtain their diplomas from the Conjoint Colleges. Jealousy of the Colleges and the unwise and ill-timed neglect of the Society by the Colleges have distorted the vision of the Master and Wardens, and unfortunately driven them to submit an opinion to the Privy Council which the mass of the profession in England will repudiate. No better explanation of the need for obtaining a new degree-conferring body for London medical students has been put forward than that contained in the first paragraph of the statement addressed to the Lord President of the Privy Council by the Association of General Practitioners:—

"With the general object of obtaining for the students of the English medical schools and hospitals who pass their examination before the licensing bodies of London facilities for obtaining a degree which shall carry with it the title of 'Doctor' the Association of General Practitioners is in entire accord. There is unquestionably a great hardship at present upon the licentiates of the London medical examining bodies, who, although possessing a curriculum equivalent to that of many of the British Universities which confer medical degrees, have nevertheless no other facilities for acquiring such a degree than those afforded by the Universities of London. The standard of the University of London is expressly placed so high as to make it unattainable for more than a small minority of the London students. It is a degree of *élite*, and placed at so high a standard as to be altogether beyond the ordinary possibilities of the average student, even when thoroughly educated and carefully examined for all the necessities of general practice. In this respect, therefore, the English students are under a great disadvantage as compared with those especially of Ireland and Scotland, and this disadvantage is practically felt because, on the one hand, large numbers of students are thus attracted to the Universities of Scotland and Ireland, where they obtain on reasonable conditions the title of M.D.; and, on the other hand, because Irish and Scotch students, who have received their degrees after an examination in no way more difficult than the average examination at present carried on in London by the examining bodies, settle in England, and practise alongside the London licentiates, with the added prestige of the degree and title of M.D., and thus claim a superior social and University status."

The new examination scheme of the Apothecaries' Society has hardly been long enough in work for that body to charge the Colleges with wishing to attract candidates by a low standard of proficiency. Such an accusation is merely

Digitized by Google

the outcome of a jealous spirit, and is ungenerous and unwise. With the contentions of both petitions otherwise—viz., that the licentiates of the Society should not be practically debarred from the privileges of a degree if this be granted to those who qualify through the Colleges, and that a wider representation, securing the presence of general practitioners on the Senate and safeguarding the interests of future graduates—we heartily sympathise, and hope that clauses will be inserted in any new Charter so that these advantages may be effectually guaranteed.

THE ROYAL COLLEGE OF PHYSICIANS AND ATTEMPTS TO POPULARISE MEDICINE.

WE understand that a certain penny weekly journal with a medical sub-title has been the subject of inquiry by the Censors Board of the Royal College of Physicians, in consequence of certain Fellows of the College having allowed their names to appear on the Council of an Association bearing a name similar to that of the journal referred to. The Censors' Board will report to a meeting of the College the result of their investigation and their opinion with reference to the attempt to popularise the science and art of medicine, by contributions to popular papers. We learn that this report was to have been placed before a meeting of the whole of the Fellows of the College in the early part of next month, but, from circumstances which have arisen, Jan. 26th is now fixed as the day on which the Censors' report will be considered, and the opinion asked of the assembled Fellows on the matter which has led to the investigation in question. We feel sure that Fellows will, at any inconvenience, attend on the occasion. We have little doubt that the respected President, Sir William Jenner, with other high office bearers, will take part in the discussion, and state their views on the causes which have brought about this inquiry. It is an open secret that the President of the Association alluded to above, after a correspondence with the College of Physicians, has unreservedly resigned all connexion both with the Association and the journal.

THE SANITARY FUTURE OF GREAT CITIES.

THERE is no more significant feature in the social history of our time than the swift and steady increase of the urban populations at the expense of that of the country. There are certainly definite advantages implied in this transference, quite apart from the question of work and wages, and these ought not to be ignored. The inborn tendency of men to congregate in towns is in itself a proof of the gain which they feel that they acquire from frequent intercourse with one another, and this may help to assure us that, with proper guidance, what seems under ordinary conditions an artificial departure from the normal mode of life may prove equally compatible with the healthy growth of mind and body. We can hardly hope to convince ourselves on this point, however, without a widespread reconstruction of our present social and sanitary arrangements. It is not to be expected that vigour of brain and muscle should characterise a people reared amid impurities, atmospheric, personal, and subterranean, such as try the endurance of those who inhabit our smoky and still overcrowded metropolis, and many another city not more happily circumstanced. The subject, as it well deserves, is attracting very general attention. Lectures and popular treatises innumerable are devoted to it year by year, and, we would fain hope in every case with some further effect than a mere inactive purpose of reform. A few days ago Mr. Frederic Harrison, in an address delivered at the Toynbee Hall, traversed almost the whole field of public sanitation as applied to cities. Necessarily his discourse was more fruitful in important generalities than in practical details; but it nevertheless conveyed some excellent advice on points which have divided the opinions both of municipal and sanitary authorities. We quite agree with his remarks on the worse than uselessness of water storage among the poorer working class of towns. The system of constant supply, notwithstanding its occasional intermissions and the possibility of waste if due care be not taken to prevent this, is certainly preferable in the interest of cleanliness and protection against disease. We should like to see it in general use among the poor, to many of whom a cistern is not very much better than a favourable specimen of cesspool. Another matter touched upon was the disposal of sewage. It must surely be allowed that the time has come to reconsider the whole of this question. The unnatural spectacle of turbid and malodorous rivers carrying with them to the sea unnumbered gallons of fluid manure, and at times mingling their impurities with water used for domestic purposes, can hardly fail, sooner or later, to impress the public mind with the advantages of any system which would convert the drain-pipe from a source of disease and offensiveness into a fertiliser of no mean order. Among the topics touched upon were the erection of model houses for artisans and the disposal of the dead. Respecting the former, there is, we allow, much to be said in favour of the tenement style in building. The suggestion that every such tenement should contain one common room for cases of infectious disease and another to act as a receiving room for the dead, though not perhaps novel, is one of evident practical value. With regard to the disposal of the dead, we trust that perseverence in the foolish and unwholesome practice of using massive, almost imperishable coffins, will not force the judgment of scientific men and of the public generally to abandon as hopeless the deserving claims of the "earth-to-earth" system. Other questions relating to sanitary reform, such as that of smoke abatement, the lighting of houses, recreation, and the like, referred to in the address before us, have been discussed in former issues of this journal, and need not now be reconsidered. Meantime we are entitled to expect that, with a stricter administration of the laws which regulate health, the extensive readjustment of population to which we have once more directed attention may prove a less doubtful benefit than it now appears to be.

MONACO AND "THE LANCET."

IN the spring of last year we published a criticism of the new sewers built in the old town of Monaco.[1] These, in consequence of the rocky nature of the ground, had cost a large sum, and were, on the whole, very satisfactorily constructed. Unfortunately, while the sewers were good in themselves, there had been no means of ventilation or flushing provided. Worse than this, there was no regulation in force to ensure that all pipes communicating with the sewers should be trapped. Yet, while these grave defects were allowed to exist, the authorities of the Principality had given manifest proofs of their desire to take all measures necessary for the preservation of public health. Subsequent events have helped to confirm this opinion. The article in question was translated *verbatim* into French by order of the Government of Monaco, and read to the Prince, who was at that time staying in France. Prince Charles at once telegraphed orders that the Commission of Hygiene of the Principality should be convoked, so as to take into consideration the criticisms published in THE LANCET, and report. This was done, with the result that the opinions we expressed were confirmed by the Commission of Hygiene. When the Prince received the report to this

[1] See THE LANCET, March 12th, 1887.

Digitized by Google

effect, he gave orders that necessary measures should be taken to provide all that was still wanting to ensure the satisfactory working of the Monaco sewers. Further than this, our Sanitary Commissioner, who recently passed through Monaco on his way homewards from reporting on the condition of Venice and Florence, was invited by the Governor of the Principality to meet the Commission of Hygiene and discuss the whole question. It was then at once decided to make experiments for the ventilation of the sewers. The compulsory application of syphons to all drain-pipes was also adopted in principle, and the question of applying automatic flush-tanks for the sewers is now being investigated. This willingness to do the best the circumstances permit is highly commendable, particularly when compared with the attitude of sanitary authorities nearer home.

THE PERILS OF FOOTBALL.

AT an inquest held at Leeds on the 23rd inst. respecting the death of George Arthur Houghton, aged nineteen years, who had died from the results of injuries received in a football match at Roundhay Park, the evidence showed that there had been a good deal of roughness all through the game. The jury, it is reported, returned a verdict of accidental death, but wished to "draw the attention of the public to the rough play that frequently took place, that the rules were not strictly adhered to, and that rules ought to be made to put a stop to such play." We need hardly point out that (with the exception of the grammar) we entirely concur with the rider of the jury. Football as too often played nowadays is brutally and unnecessarily rough and dangerous. The game—in itself a good game and capable of much good in the interests of health—seems to be degenerating rapidly into what is little less than a "free fight," at which serious accidents are common and fatalities by no means unknown. It is not only the injured player who suffers; he is often a bread-winner who can ill be spared. As we have said before, if football cannot be very considerably "mended" it must be "ended." The authorities who preside over the two styles of the game seemed to be bestirring themselves some little time since. Have they again gone to sleep?

CATARRH OF THE ANTRUM.

IN cases of catarrh of the antrum, Dr. Schiffers of Liège, instead of extracting the second molar, gains access to the cavity through the opening in the middle meatus of the nose. Through this he inserts a director, and with the help of a curved probe-pointed bistoury he opens up a passage for the free exit of the confined secretion. By the use of cocaine the patient suffers but little during the operation. Dr. Schiffers points out that catarrh of the antrum is frequently overlooked and mistaken for an affection of the nasal mucous membrane. When an abundant fetid discharge runs from the nose, especially when it is intermittent, the existence of disease of the antrum should be suspected, and a careful search made, with the help of the nasal speculum and a good light, for the welling up of the secretion through the foramen in the middle meatus.

ARE ASSES CAPABLE OF VOMITING?

AN interesting physiological point is now being discussed in Paris. M. Zola, in his last work, "La Terre," depicts an intoxicated ass, and concludes with an account of the animal in the throes of sickness. M. Sarcey has taken offence at this unpleasant piece of realism, and in a review of the work affirmed that the ass was incapable of being sick, and brought forward the evidence of a veterinary [illegible] to the effect that the structure of the [illegible] renders vomiting impossible. M. Zola writes back and turns the tables on his adversary by stating that he had read up the principles of equine or asinine physiology before venturing to describe the matter in question, and refers the veterinary surgeon to his studies. In point of fact, M. Zola is perfectly correct. It is commonly but incorrectly asserted that the horse and ass cannot vomit. It is true that they vomit rarely and with great difficulty, the reasons being that the stomach is small, that the œsophagus opens into the stomach much nearer the pylorus than in the dog or man, so that the cardiac portion forms a large sac, against which the contents of the stomach are pressed when efforts to vomit are made. The contents of the stomach are, moreover, usually rather dry, and do not remain long in the interior of that viscus, and finally the œsophageal aperture is small and highly muscular. The latter point is undoubtedly of importance, since horses, and we presume asses also, vomit readily enough when by disease or operation the cardiac sphincter is paralysed. M. Zola, if not very delicate, at least studies his art.

THE SMALL-POX EPIDEMIC IN YORKSHIRE.

THE small-pox epidemic in Yorkshire is assuming serious proportions. In Sheffield the disease, having slumbered through the early months of summer, increased rapidly about August. In September 275 fresh cases were reported; in October there were 498; in November, 604; and up to December 19th 585 more became known, and this without compulsory notification. Indeed, it is well known that some of the mildest cases are not heard of, and since it is so difficult to control the movements of persons thus attacked, these mild cases constitute the greatest source of danger to those who are either imperfectly or not at all protected by vaccination. In view of these facts the borough hospital soon filled; then came a grave suspicion that the disease was being exceptionally diffused in the vicinity of this hospital, and under these circumstances another was established elsewhere. The Corporation were then threatened with legal proceedings, and, the case ultimately coming before the law courts, the judge, acting on the advice of Dr. Buchanan of the Local Government Board, instructed Mr. Shirley Murphy to report on the case to the Court. That report expressed the view that there was an element of danger to the inhabitants, and on this an injunction was granted. Now, at last, a site of forty-two acres within the borough has been found, and although the locality is very exposed, yet Dr. Parsons has reported to the Local Government Board that it is a suitable one. This was announced the other day at the public inquiry, when a loan of £13,000 was asked for the purchase of the site, and the erection thereon of wooden huts to accommodate sixty patients in the first instance; an instalment that can only be expected to mitigate and not prevent the extension of an existing epidemic from which 800 to 1000 persons are now suffering. The sanitary authorities comprised within the Barnsley Union are also face to face with the prospects of an epidemic, the disease being already in Wath, Worsborough, Ardsley, Hoyley, and Wombwell. The Corporation of Barnsley have offered to receive in their hospital cases from the [illegible] townships, and at a recent meeting representatives of the various authorities decided to leave the question of future extension in the hands of the Corporation. In Leeds also the disease is further extending, and in several [illegible] around the larger boroughs cases have [illegible]. Bradford is also making certain preliminary [illegible] as to isolation in case the disease [illegible] the union; and at a recent [illegible] to the effect that the structure of the [illegible] it was explained that [illegible]

Digitized by Google

paupers should be sent to the Bradford Fever Hospital, for, quite apart from the fact that the workhouse infectious building was already full of scarlet fever and measles, that place was not a proper one in which to aggregate small-pox patients. We would earnestly urge all who have not been vaccinated within recent years, or who show imperfect marks of vaccination, at once to seek revaccination. There is no greater mistake than to leave this until the existence of small-pox is actually ascertained to be at hand. Efficient revaccination is more difficult than efficient primary vaccination, and it needs well-selected fresh lymph taken direct from the arm. Such lymph cannot be instantly manufactured, and hence it is important that the regular weekly vaccination station should be the main centre for the performance of revaccination, and this before there is a panic and a consequent run on the public vaccinator for lymph beyond that which he can properly supply.

INTESTINAL AFFECTIONS OF YOUNG INFANTS.

DR. TH. ESCHERLICH of Munich, writing on gastro-intestinal affections in children, points out that when the small intestine is the seat of the disorder, as this is inaccessible to washing out, like the stomach and colon, the best way to act upon it is to regulate the food so that the contents of the small intestine shall not easily undergo fermentation. He mentions the researches of Hirschler, which show that in a mixture of albuminoids and carbo-hydrates, such as milk, the carbo-hydrates are the first to decompose. When, therefore, acid fermentation is going on, the carbo-hydrates should be removed from the diet. Similarly, when albuminoid fermentation processes are going on, as shown by the occurrence of offensive stools, the addition of small quantities of dextrin or other carbo-hydrates to the diet may be expected to stop the albuminoid fermentation.

A FLOATING HOSPITAL FOR THE NORTH SEA.

THOSE of us who live within a stone's throw of a trusted medical practitioner can form some idea of the comparatively forsaken condition of dwellers in rural districts from whom surgical and medical aid, so needful in emergencies, is removed by several miles of indifferent country road. Can they, we would ask, have any true idea of the case of fishermen at sea, who, in the event of injury or illness, may have to suffer for days unaided save by the kind but rough-and-ready leech-craft of their fellow-smacksmen? If they can, it is hardly possible that they will refuse their support to the scheme for providing a floating hospital for the benefit of this hitherto neglected class of men. Several circumstances combine to enforce their claim upon public consideration. The number of those employed is not small. Some twelve thousand men are said to constitute the English-speaking portion of the floating population in the North Sea alone. These will constitute the allotted charge of the hospital ship. Separated they often must be over this wide cruising ground, either by the necessities of their calling or by stress of weather. The fishing vessels, however, in virtue of their very multitude, have something of the cohesion which belongs to a fleet—an important practical point in connexion with the proposed scheme. We must not forget the value to the country of those who navigate them. Whether as makers of our commercial prosperity or as pillars of national defence, their energies are well worthy of preservation, while the perils which threaten them are neither few nor light. If we grant the possession, to begin with, of more than average powers of endurance, we have at the same time to reckon with surroundings which are unusually adverse. The battle of angry elements is but one danger. From this and other sources arises a variety of causes of accident. Illnesses of the inflammatory type also have here every condition favourable to their rapid and vigorous development. Delay in such cases may—and without doubt often does—adversely turn the scale between life and death. We have, therefore, under all these circumstances, a special satisfaction in casting this project, as one of the best we have known, upon the good-will of all our fellow-countrymen. A ship cannot be acquired and fitted as a hospital without an ample outlay of money. It is equally evident, however, that the cost of such an undertaking is by no means unlimited. Its pressure when distributed over many subscribers will hardly be felt by individuals, except as a sense that "the heart grows rich in giving," and the good which it is likely to accomplish is incalculable.

FREE COOKING STOVES AND FREE BATHING PLACES.

IT is asserted, and with much show of reason, by the correspondent of a contemporary, that the two most urgent needs of the poorer classes, just now, are free cooking stoves or ranges, and free bathing places. Without doubt, these are important matters; and it is easy to see that if the poor could have ready access to a good cooking apparatus, they might be instructed and enabled to make better use of the food their limited means may procure, and thus find their meagre pittance of higher value in the way of sustenance, and it does not require any laboured argument to demonstrate they must be happier and healthier if they are less dirty. Even a penny is a large sum for a really poor person to pay for a bath. It would be well if the luxury, which is also a necessity, could be provided gratuitously. To be of practical usefulness, the free cooking stove and the free bath must be close at hand. It would be a philanthropic enterprise to provide such conveniences in the very centres of the most populous districts.

THE MEDICINE STAMP DUTY.

THE legislative duties of the year 1888 may be said in a sense to have already commenced, for although there are still a good six weeks before the meeting of Parliament, the season of Cabinet Councils has opened, and the Government has sufficiently matured its plans to be able to make public promises that the forthcoming session shall be chiefly devoted to the discussion of measures in which England, Scotland, and Wales are directly and principally interested. We hope that it may be found possible to redeem the pledge, for there is plenty of work ready to the hand of Parliament within the sphere of most strictly domestic politics. Several measures which we have long advocated await only the leisure of the House of Commons, and foremost among these we should for our own part place the repeal of the medicine stamp duty. We have so recently discussed the whole subject that it would be tedious and inopportune to renew the discussion here and now, but we notice with great satisfaction that the demand for repeal is increasing on every hand, and was recently re-echoed by our contemporary the *Saturday Review* in the eleventh of a series of special articles upon quack medicines which is now appearing in its pages. The grounds taken by this latest exponent of the sound doctrine on this point are exactly those which we have ourselves assumed—namely, (1) the enormity of the fraud to which it gives rise, and the ignominy which it brings upon the Government which in any way connives at it; and (2) the fiscal objection to a scheme of taxation which takes from the taxpayer four times the amount which it yields to the Treasury. Indeed, it is impossible that such cogent arguments should not be advanced, and advanced into the very forefront of the discussion, whenever it is brought on; and

Digitized by Google

when these arguments have been driven home to the understanding of Parliament and the country, they will certainly make a speedy end of this barbarous relic of the Georgian era. In one respect the present time is singularly promising, for it cannot be supposed that a publicist like Mr. Goschen will fail to appreciate the weight of the objections to this tax on which we rely, and we are accordingly disposed to hope much from his next Budget provisions.

RESIGNATION OF SIR ROBERT RAWLINSON, C.B.

IT is with feelings of genuine regret that we have heard of the resignation of Sir Robert Rawlinson, C.B, Chief Engineer to the Local Government Board. It is not that he has not earned the repose of retirement from official duties, for there are few men who have reached the age of seventy-six who can look back with more pride and satisfaction to the labours of a useful life than Sir Robert Rawlinson. Our regret lies mainly in the fact that Sir Robert finds that his years are telling on him, and that a recent indisposition has given him hints that he must take more care of himself than he has hitherto found it necessary to do. Having first studied railway engineering, and then having taken the post of assistant surveyor to Liverpool, Sir Robert was next engaged by Government to advise them as to the terrible sanitary state of the camps, barracks, and military hospitals during the Crimean War. Then, during the cotton famine in 1863, he organised great relief works in Lancashire, and his extremely able services were at this time recognised by the bestowal of a C.B. Later on he was appointed to the office he now quits; he also served as Royal Commissioner on several occasions; and in every position in which he has been placed he has done good and lasting work, and won to himself a large circle of friends. His mind is too active to allow of a useless close, and we trust that he will find many an opportunity still further to advance the cause of sanitation, which he has so much at heart.

MYOPIA.

A VERY sensible decree has just been issued by the Austrian Minister of Public Instruction, forbidding the use of books printed with small type in public schools, as short-sightedness is so prevalent amongst school children in Austria. Scientific supervision might very properly be given to school books in this country, attention being especially directed to the size of the type, length of line, and spacing of letters and lines. In the works published by the Clarendon Press no fault can be found in these respects, and, speaking generally, the school books of this country are well printed. The chief fault in German books is their adherence to the very dazzling Old English shape of the letters, which certainly severely tries the eyes by necessitating very close attention, and the evil effects of this is aided by the paper being coarse and by the light supplied being usually insufficient.

CHRISTMAS FESTIVITIES AT THE METROPOLITAN HOSPITALS.

CHRISTMAS DAY was celebrated in the various metropolitan hospitals with but few exceptions by the substitution of the orthodox fare for the usual hospital rations, and the wards of the various institutions were gaily and tastefully decorated. In consequence of the festival falling on a Sunday the usual gaieties and pastimes of the season took place on the following day, and at Guy's Hospital, except for the decoration of the wards, the 25th was observed as an ordinary Sunday, the Christmas dinner being postponed until the 26th inst. Distributions of toys to the younger patients, and of clothing and useful articles to adult sufferers, [illegible] also made [illegible]

THE SENSE AND SENSES OF ANIMALS.

SIR JOHN LUBBOCK recently devoted a lecture to this subject in Queen-street Hall, Edinburgh, and pointed out that the dog was generally admitted to be a loyal, true, and affectionate friend of man, but, when the nature of the animal was considered, our knowledge, he said, was very limited, and this arose from the fact that attempts were made to teach animals rather than to learn from them. It had occurred to him that some such method as that which was followed in the case of deaf-mutes might prove instructive if adapted to the case of dogs. He had tried with a black poodle belonging to himself, and had made the following experiments:—

"He had taken two pieces of card, one blank and the other with the word "food" upon it. He had put the latter on a saucer containing some bread and milk, and the blank card he put on an empty saucer. The dog was not allowed to eat until it brought the proper card to him. This experiment was repeated over and over again, and in about ten days the dog began to distinguish the card with the letters on it from the plain card. It took a longer time to make the dog realise the difference between different words. In order to try to discover whether the dog could distinguish colours, he prepared six cards, marking two of them blue, two yellow, and two orange. He put one of each on the floor, and tried to get the dog to bring to him a card with the same colour as one which he showed the dog in his hand. After trying this for three months, he found that his experiment in this direction was a failure."

Sir John Lubbock proceeded to state that he considered it to be doubtful whether ants could hear, but that it was possible both they and bees might hear sounds so shrill as to make no impressions on the human organ of hearing; and so perhaps with colours. The world might to insects be full of music we could not hear, colours which we could not see, and sensations which we could not feel.

FEVER IN LONDON.

THE number of patients admitted into the hospitals of the Metropolitan Asylums Board during the week ending Dec. 23rd was 143 suffering from scarlet fever, and 15 from enteric fever. No case of small-pox or of typhus fever was received during this period. The deaths from scarlet fever during the preceding week were 11·6 below the corrected average for the same week of the last ten years; the deaths from diphtheria were 5·7 and from whooping-cough 5·5 above the average. It is stated that the Metropolitan Asylums Board has submitted plans to the Local Government Board for the building at Darenth of a "brick hut" hospital for 600 convalescent small-pox patients, the administrative buildings to be equal to supplying 1000 patients; it is estimated that the total cost will amount to £58,900, and it is argued that this would be a more economical method of construction than if the huts were constructed of wood instead of brick.

ISOLATION ARRANGEMENTS AT COLCHESTER.

AT Colchester the guardians very properly desire to make some arrangements with the corporation as to the isolation of infectious paupers. They have wisely decided that duplicate hospitals would be a mistake; that the workhouse is not a proper place in which to aggregate the infectious sick. They are also seeking to learn how far the demand which the Leeds guardians recently made upon the corporation of that borough, that paupers should be admitted into the sanitary hospital as a matter of right, can be maintained. So far, the demand in question is, as we [illegible] only based on counsel's opinion, but the [illegible] of the law officers of the Crown, [illegible]

Digitized by Google

THE CROWN PRINCE.

THE latest reports from San Remo are more favourable than they have been, so far as the immediate future of the Crown Prince is concerned. A swelling noticed a short time ago has subsided, and this has given rise to optimistic rumours. This was probably œdematous in character, although Sir Morell Mackenzie is reported to have spoken of it as the cicatrisation of a cancerous growth, which he states does occur in the larynx. On the other hand, "another slight tumour" has been discovered, and this fact would seem to show the correctness of the diagnosis arrived at in November. Sir Morell Mackenzie has stated that "time only can show us the exact nature of the Prince's ailment." This statement does not very clearly indicate whether he still entertains a doubt as to the malignancy of the growth, or as to the degree of malignancy. At any rate, the evidence, so far seems to show that we may hope that the disease, if it be cancer, is of the less malignant form.

TORRENS' ACT.

AN important decision has recently been given by Mr. Baron Pollock in the Queen's Bench Division of the High Court of Justice on the question of the ownership of property concerning which a local authority had taken action under the Artisans and Labourers' Dwellings Act of 1868. A leaseholder received from the vestry of Marylebone notice relating to certain houses which he held on a long lease almost expired, but concerning which arrangements had been made for the lease to be renewed for a further term of twenty-one years. An order was then made for the demolition of the property, but this was amended on appeal, and the owner was ordered to put the premises in proper repair. For this purpose some of the work required to be done was in excess of the leaseholder's covenants to repair, and the leaseholder therefore communicated with the freeholder, carried out the work, and obtained a charging order on the premises. The freeholder subsequently appealed on the ground that the leaseholder's interest had nearly expired, and the case depended upon whether anyone who was the owner when the notice was given could cease to be the owner within the meaning of the Act when the order was subsequently made. Mr. Baron Pollock said it was impossible to suppose it was the intention of the Legislature to enable a person to whom notice had been given to get rid of his liability before the order was made by saying that his interest had run out, and that the object of the Act was to call upon the person who was the owner at the time the defective condition of the premises was discovered to put them into a proper state. He gave judgment accordingly.

UNHEALTHY HOUSES AT PLUMSTEAD.

A CORONER'S JURY at Plumstead have very properly requested that the attention of the Local Board should be directed to the disgraceful condition of some of the newer parts of the parish. It is said that there is in the neighbourhood a great demand for cheaply rented artisans' dwellings, and these have recently been run up literally by the thousand, being let or sold and inhabited before they are finished. The tenants themselves are usually so eager to enter that they do not think of stopping to make objections that the houses are built upon land which, it is alleged, has been the depository of refuse, and that the roadways are mere masses of unwholesome mud. When people will not protect themselves, it is surely necessary for the local authorities to exercise a more paternal government than they do at present. If the Plumstead Board would take counsel with their medical officer they would certainly receive some valuable hints as to the sanitary condition of many of the new streets. The jury appears to have felt somewhat strongly on the subject, as the case was not one directly due apparently to insanitary surroundings. The child seems to have died rather suddenly, medical evidence going to show that uræmic poisoning due to Bright's disease, consequent possibly on an overlooked attack of scarlatina, was the cause of death.

THE GRAND JUNCTION WATER COMPANY.

ONE of the great London water companies proposes to alter the source of its supply. The Grand Junction Company intends, we are informed, to apply for Parliamentary powers to remove its in-take to Dorney in Buckinghamshire, a spot above Windsor. It is impossible to decide offhand whether such an alteration would be an improvement. Recent pollution in water is most to be dreaded, and the surroundings of the new in-take will require careful consideration. But it seems probable that the proposed change will be beneficial, for there is comparatively little risk of pollution in a district which contains few river-side dwellings, and there is a good chance of self-purification by oxidation in water which flows to the consumer through a long channel.

THE BRITISH PHARMACOPŒIA.

EVEN the British Pharmacopœia is provided with a champion who defends its contents. Professor Redwood is that champion, and his arguments published in the *Pharmaceutical Journal* seem to have demolished the adverse statements of Professor Tichborne, who represents as fundamental errors the system of weights and measures, specific gravities, and volumetric estimation of the British Pharmacopœia.

SUFFOCATED INFANTS.

THE coroner for East Surrey seems to have held inquiries into the cases of not less than eight infants suffocated on the night of Christmas Eve or the morning of Christmas Day. This represents a serious mortality. It is extremely regrettable that those who have the care of children of tender age do not feel their responsibility sufficiently. Attention ought to be pointedly called to the need of special carefulness, and district medical officers might help in making the facts known, and giving good and warning counsel.

FOREIGN UNIVERSITY INTELLIGENCE.

Breslau.—The hundredth birthday of the celebrated veteran anatomist and physiologist, Johann Evangeliste Purkinje, has just been celebrated.

Rostock.—The Mecklenburg Landtag has voted £15,000 for the enlargement of the hospital and for the erection of an eye department.

THE PUBLIC VACCINATOR FOR CARDIFF.

THE *Western Mail* for December 26th gives an account of the meeting of the Board of Guardians of Cardiff, at which it was decided to terminate the contract with Mr. Horder, the public vaccinator for the town. The charge against Mr. Horder was that he was unwilling to supply three practitioners with lymph for the vaccination of their patients; but it is now shown that he did in fact supply two of them, and that he had ample reason on account of shortness of his own stock for not supplying the third. Mr. Spear, medical inspector of the Local Government Board, testified to the efficiency of Mr. Horder's work, but without avail, and, as we read it in the local journal, an act of very serious injustice has been done to the public vaccinator. If the guardians of Cardiff have any self-

Digitized by Google

respect they will not leave the matter where it is, but will carefully investigate the whole circumstances of the case, and unless something far more serious can be proved against Mr. Horder than has hitherto transpired they will, we trust, feel that no public officer should be deprived of his appointment for reasons so frivolous and evidently so groundless.

SIR WILLIAM JENNER.

A REPORT has appeared in some of the morning papers to the effect that Sir William Jenner was suffering from illness. We are glad to be able to state authoritatively that he has only been labouring under what is popularly known as "a bad cold." He is now quite well.

WE regret to record the death, on the 24th inst., of Dr. Ross, of Portree, Skye, from typhus fever. The deceased, who was highly respected throughout the Island, leaves a widow and four children.

THE CONTAGIOUS DISEASES ACTS.

By J. H. PARKER WILSON,
MEDICAL OFFICER, H.M. MILITARY PRISON, BRIXTON.

HAVING watched with considerable interest the discussions that are constantly taking place in THE LANCET relative to the contagious diseases, I thought it would not be without interest to bring before the notice of the profession a carefully compiled return for the years 1884–5–6, dating from about the time when the Contagious Diseases Act ceased to be enforced. Considering the large number of men who pass through this establishment annually, and are under my medical care, an unusually favourable opportunity is afforded me of estimating how rapidly a disease,

TABLE I. (1884.)

which has proved to be so much under control, can break out afresh, and to show the ever-increasing ravages it may produce. In the face of so-called philanthropy and sham sentiment, it does not appear that any facts will make any alteration in the views of the question held by the public; but to my professional brethren some important items which relate to the class of men who come more especially under my observation will, I feel convinced, be of great interest. It should be borne in mind that at the early age in which soldiers are drafted into the ranks, they are easily led away by temptation, being naturally more under the influence of sexual passion, and so fall an easy prey to the miserable wretches who ply their trade about all barracks and garrison towns, and at a very early age may thus become diseased and a source of constant contagion. This being the case, it is no doubt highly desirable that stronger steps to prevent contagion than are now in force should be taken to cope with this frightful scourge. Under the old system of long service, a soldier once infected had perhaps his whole

life before him in the service, where he would have careful medical supervision and treatment; whereas at present he may contract the disease shortly before the expiration of his term of service, and be then a very young man; and not having had time or opportunity to be treated or in any way cured of his disease, he is cast on the community at large, where he not only has further chances of disseminating it,

but may marry and infect his unhappy wife, propagating a race of diseased children through many generations.

It is not my intention to enter into the several forms of the disease which have come under my care, but one cannot avoid being forcibly impressed with the fact that after the Contagious Diseases Act had been in force the diminution

Digitized by Google

of the complaint was most marked and the more virulent forms of the disease considerably lessened.

The accompanying tables will show the different localities whence the diseases were contracted, and in their arrangement the utmost care has been exercised to ascertain that the forms of disease were typical. Some explanation of the arrangements of the tables may perhaps be advisable, otherwise there will appear to be discrepancies in more than one of the entries. For instance, in the table for 1884 (No. I.) the following entry appears: "Aldershot—gonorrhœa 5; syphilis 8; total infected 13; number of men received from the station 8." Without explanation there would at once appear to be an error in this record, the number shown as infected being greater than that received from the station. The explanation is as follows: Eight men were received from Aldershot, all of them infected; but the other five, although they contracted the disease originally at Aldershot, had been transferred to other military stations, whence they were received here. Of all the military stations from which my experience is derived, the worst forms of the disease have existed in those men who have become infected at Canterbury, and it will be seen that in 1885 the percentage was unusually high.

SUMMARY OF TABLES.

Year.	Number of men infected with gonorrhœa.	Number of men infected with syphilis.	Number of men infected with both diseases.	Percentage of men infected with gonorrhœa.	Percentage of men infected with syphilis.	Percentage of men infected with both diseases.	Number of men received each year.

REPORTS UPON LUNATIC ASYLUMS FOR 1886.

THE report of the Superintendent of the West Riding Asylum at Wakefield states that the admissions during the year numbered 447, and that the discharges and deaths together exactly balanced this number. Of the 447 fresh cases, 331 were admitted for the first time, and the remaining 116 had previously been under care in the asylum. Comment is made upon the large number of admissions of males in the last stage of general paralysis or sinking from pulmonary affections. Many of these, it would appear, did not require the special care of an asylum, but might have been judiciously treated at home or in the neighbouring workhouse. The rate of mortality was 12·64 per cent. among the males, and 8·45 among the females. One epileptic was suffocated by turning upon his face during a fit. In this case, the usual precaution had been taken by providing an epileptic pillow, but nevertheless the patient was found lying with his face upon it. The percentage of recoveries on the total admissions was 43·62. The occurrence of some cases of typhoid fever is attributed to "the disturbance, by the new drainage operations, of germs which had remained latent from former cases of typhoid."

In his report on the Kent County Asylum at Barming Heath, the Superintendent, referring to the increase in numbers, says that it is explained by the diminution of discharges. He is of opinion that the general depression in trade and industry of all kinds, which has been so severe lately, has directly conduced to this result, and this in two ways: firstly, by lowering the vital power of those affected; and, secondly, by curtailing the means of the patients' friends, thereby rendering it impossible for them to do anything towards promoting recovery, by removing the patients early and completing their cure at home. He has great faith in their early removal from an asylum. Let their wards be ever so cheerful, they lack the nameless comforts of home, and relapse but too frequently ensues if removal be unduly delayed. The death-rate was 12·1 per cent. on the average number resident; the proportion of recoveries to admissions was 43·6. No recourse was had to seclusion or mechanical restraint during the year.

The report of the Wilts County Asylum states that the county is to be congratulated on having an almost stationary insane population, and that it is further fortunate in possessing sufficient accommodation for its own lunatics. The Superintendent says that the cases admitted become of a more and more unfavourable class, especially the men. The death-rate was 12·5 per cent., and the percentage of recoveries on admissions was 27·5.

The Superintendent of the Royal Edinburgh Asylum deals in a very practical manner with many points bearing on insanity in its social relations. Dealing with the question of the nature of the habitation which an asylum ought to provide for its inmates, he says: "It is now generally admitted that for a number of patients we cannot get classification and individualisation enough, if the whole institution is under one roof. We need distinct homes, and houses of different kinds. Many of the patients are capable of living ordinary lives in ordinary houses, *plus* medical supervision and skilled attendance. We need all through the *hospital* and the *home* idea—the hospital and its special arrangements predominating for patients in one state of mind, and the home for others in a different state." The death-rate was 7·7 per cent.; and the recovery-rate on admissions was 38·5 per cent.

The report of the Superintendent of the Richmond District Lunatic Asylum reveals an almost incredible condition of things. "The sanitary state of the institution is deplorable. The watercloseets throughout are in a sad state. In the North (male) House there are in one group of wards no watercloseets whatever that are accessible for day use, and the only accommodation for 120 men is one earth chair." Under such circumstances, it is not surprising to find that out of an average population of 1076 as many as 117 were under hospital treatment for diarrhœa and dysentery during the year, or to find that these diseases caused twenty-two deaths in the same period; while for the past ten years they have caused an average of twenty-six deaths annually. "Erysipelas is rarely absent from the house, and in some years has caused a considerable number of deaths. This state of things demands remedy, and the newly appointed superintendent deserves every support in his attempt to put matters on a satisfactory footing. The percentage of deaths on the daily average numbers was 14·8, and that of recoveries on admission was 30.

The Superintendent of the Gloucester County Lunatic Asylums at Wotton and Barnwood states in his report that the admissions were fewer in number than in any year since 1878, but that they included a large proportion of male suicidals and epileptics requiring continuous supervision by night. The recovery-rate was 45 per cent. on the admissions, and the death-rate was 12·2 on the average number resident. The Superintendent is doing well in directing his attention to the supply of efficient means of warming all the dormitories and wards.

The report of the Superintendent of the Cheshire County Asylum at Macclesfield refers to a large decrease in the admissions from the Cheshire unions, and also to a very satisfactory financial condition upon a surprisingly low actual cost per head per week (little over 8*s.*). The recovery-rate was 46·2, and the death-rate was 17·7 for males and 7·9 for females. The high rate of mortality among the men is accounted for by an unusually large number of deaths from diseases of the nervous system.

The Superintendent of the City of London Asylum calls attention to the great age that had been reached by a number of the inmates who had died during the year after long periods of residence, "showing how life may be prolonged under conditions of complete rest and sufficient food."

The Superintendent of the Crichton Royal Institution at Dumfries reports that for some years he has observed what seems to be a change in the duration of general paralysis. "Ten or fifteen years ago, from two to three years was considered the limit of life in men after its symptoms were decidedly pronounced. At present there are several men, undoubted general paralytics, who have been ill for upwards of four years, and are yet in good physical condition. The less rapid course of the disease may be due to improved methods of treatment or nursing, or perhaps to its having been brought on by slighter causes than prevailed in those we were accustomed to see long ago; if so, this would account for the increase in the number of such cases. Another feature in the nature of the admissions now, as compared with ten

Digitized by Google

years ago, is the small number of cases of acute mania and the large number of those of mental depression or melancholia." The percentage of recoveries on admission was 44, and of deaths on the average number of residents 6·4. A memorandum by the General Board of Lunacy is given with regard to an inquiry held as to the charges brought against the management of the Second House of the institution. The allegations were not borne out, but disproved, and a favourable report as to the management was presented by the Lunacy Commissioners.

The report of the Superintendent of the Leicestershire and Rutland Asylum shows that of the 64 inmates who died, 28 were between sixty and eighty years of age, and 4 between eighty and ninety. The rate of mortality was 13·9 per cent. on the average number resident. Of the deaths, 13 were due to senile decay, 21 to diseases of the brain, and 23 to pulmonary and cardiac affections.

The Superintendent of the Derbyshire Asylum reports that "all patients, when practicable, are weighed on admission, and for several years past it has been the practice to weigh all the patients in the house every month." This is a very laudable practice, and it is a great help to the medical officers in their endeavour to detect any downward tendency in the health of their patients. The recovery-rate was 43·10 per cent. on admissions. The death-rate was 12·6 per cent. on the average number resident. The high death-rate is attributed to pulmonary consumption and to the unfavourable character of the cases admitted. More than half the deaths occurred in those who had been resident under twelve months, whilst as many as eighteen were admitted and died the same year. The experience of the "special single boiler fuel economiser" has fully confirmed its usefulness, and has shown that it effects a considerable saving in fuel.

The Superintendent of the Devon Lunatic Asylum says: "The marked falling off in the number of admissions in the last two years is a noteworthy fact, but is not easily accounted for. In the present uncertain and transitional state of the Lunacy Laws, both magistrates and medical men are reluctant in many cases to make the necessary orders and certificates for admission to the asylum. The movement of population in agricultural districts may also be an important factor, as the tendency is for a certain proportion of the rural population to remove to urban districts or to emigrate." The percentage of recoveries on admissions was 35·82; that of deaths on the average number resident 10·1. A very interesting statement is given of the deaths quarterly in relation to the state of the weather, and it points to the necessity for an efficient system of warming the galleries, day rooms, and dormitories in asylums.

The Superintendent of the Wonford House Hospital for the Insane is "again able to give a favourable account of the general health of the establishment, especially in regard to the immunity from what may be termed preventable diseases." The percentage of recoveries on admissions was about 45, and of deaths on the average number resident only 3.

DURHAM UNIVERSITY AND MEDICAL DEGREES.

AT a Convocation held at Durham on the 20th inst. the following petition to the Queen was agreed to:—

To the Queen's Most Excellent Majesty in Council.

The petition of the Warden, Masters, and Scholars of the University of Durham humbly showeth:—

That, whereas the Royal College of Physicians of London and the Royal College of Surgeons of England, acting in conjunction, have applied to your Majesty's most honourable Privy Council for a Charter for power to confer degrees in Medicine and Surgery. That the united Colleges would be a degree-conferring body constituted by one faculty, namely, Medicine and Surgery in combination, hence it would be an incomplete university. That the degrees would be conferred after a course of study and examination less comprehensive and advanced than that which is in force in the existent universities of England, and in consequence, the knowledge and attainments of the recipients of the degrees would be a lower standard than that of the medical graduates of the existent universities. Such an influence would be distinctly retrogressive to the medical profession. That the proposal to confer degrees in Medicine and Surgery "on persons who, by passing the examinations formerly held by both of the said two Colleges separately, or by passing the examination held by the Examining Board of the two Colleges, or by passing any other examination to be held by the two Colleges jointly or separately, have already acquired or may hereafter acquire the qualification for registration under the Medical Act," would be an innovation on the established practice of the universities, as the degrees would apparently be conferred without any further examination than the ordinary examination for members and licentiates. That in Edinburgh, Glasgow, and Dublin there are at present institutions corresponding to the Colleges in London, and, if the privileges sought should be granted, the institutions specified, exercising usual power, might justly claim the same new privileges, to the serious detriment of the universities in their influence on medical education and examination. That an incorporated body, under the name and style of the Senate of Physicians and Surgeons, "with power to grant to persons who have obtained qualifications under the Medical Act, and shall be otherwise properly qualified, degrees in Medicine and Surgery," is unnecessary, as the existent universities of England—namely, Oxford, Cambridge, Durham, London, and Victoria—are amply sufficient for the requirements of the medical profession. Your petitioners, therefore, most humbly pray your Most Gracious Majesty not to accede to the application, in the belief that, if this privilege was conceded, it would prove to be injurious to the public and the medical profession, and that they may be heard in support of the allegations of their petition.

And your petitioners will ever pray, &c. W. C. LAKE, Warden.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN twenty-eight of the largest English towns 5333 births and 3679 deaths were registered during the week ending December 24th. The annual rate of mortality in these towns, which had been 21·1 and 22·1 per 1000 in the preceding two weeks, declined last week to 20·8. During the first twelve weeks of the current quarter the death-rate in these towns averaged 20·8 per 1000, and was 1·1 below the mean rate in the corresponding periods of the ten years 1877-86. The lowest rates in these towns last week were 15·5 in Derby, 18·6 in London, and 19·1 in Bradford and in Norwich. The rates in the other towns ranged upwards to 28·9 in Manchester, 30·4 in Plymouth, 31·3 in Leicester, and 31·7 in Blackburn. The deaths referred to the principal zymotic diseases in the twenty-eight towns, which had increased from 443 to 500 in the preceding three weeks, declined again last week to 455; they included 145 from whooping-cough, 91 from scarlet fever, 79 from measles, 47 from "fever" (principally enteric), 47 from diphtheria, 23 from small-pox, and 23 from diarrhœa. These zymotic diseases caused the lowest death-rates last week in Brighton, Portsmouth, and Huddersfield, and the highest rates in Derby, Wolverhampton, Bolton, and Sheffield. The greatest mortality from measles occurred in Bradford, Birmingham, Bolton, and Derby; from scarlet fever in Wolverhampton, Plymouth, and Birkenhead; from whooping-cough in Salford, London, Wolverhampton, and Leicester; and from "fever" in Wolverhampton. The 47 deaths from diphtheria in the twenty-eight towns included 24 in London, 5 in Manchester, 2 in Birmingham, 2 in Liverpool, 2 in Sheffield, 2 in Hull, and 2 in Cardiff. Small-pox caused 21 deaths in Sheffield and 2 in Bristol, but not one in London or in any of the twenty-five other large provincial towns. The metropolitan hospitals receiving cases of small-pox contained 5 patients on Saturday last, against 9 and 10 on the preceding two Saturdays. The number of scarlet fever patients in the Metropolitan Asylum Board hospitals and in the London Fever Hospital at the end of the week was 2295, against numbers declining from 2764 to 2499 on the preceding four Saturdays; the cases admitted also showed a further decline from the numbers in recent weeks. The deaths referred to diseases of the respiratory organs in London, which had been 408 and 413 in the preceding two weeks, declined last week to to 357, and were as many as 185 below the corrected average. The causes of 80, or 2·2 per cent., of the 3679 deaths in the twenty-eight towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Brighton, Portsmouth, Norwich, Wolverhampton, Birkenhead, Bradford, and Sunderland. The largest proportions of uncertified deaths were recorded in Derby, Salford, Preston, and Halifax.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 22·7 and 23·0 per 1000 in the preceding two weeks, declined again to 22·4 in the week ending Dec. 24th; this rate, however, exceeded by 1·[illegible] the mean rate during the same week in the [illegible] large English towns. The rates in the Scotch [illegible] from 11·3 and 17·8 in Perth and Greenock to [illegible] in Paisley. The eight towns last week showed a decl[illegible]

Digitized by Google

amber in the preceding week, and included 25 which were referred to whooping-cough, 17 to measles, 17 to "fever" (typhus, enteric, or simple), 13 to scarlet fever, 4 to diphtheria, 4 to diarrhœa, and not one to small-pox; in all, 80 deaths resulted from these principal zymotic diseases, against 69 and 75 in the preceding two weeks. These 80 deaths were equal to an annual rate of 3·2 per 1000, which exceeded by 0·6 the mean rate last week from the same diseases in the twenty-eight English towns. The fatal cases of whooping-cough, which had been 29 and 26 in the previous two weeks, further declined to 25 last week, of which 13 occurred in Glasgow, 3 in Edinburgh, and 3 in Leith. The deaths referred to measles, which had been 12, 14, and 15 in the preceding three weeks, further rose to 17 last week, and included 11 in Edinburgh and 5 in Dundee. The fatal cases of "fever," which had been 5 and 9 in the previous two weeks, further rose last week to 17, of which 14 occurred in Paisley and 3 in Glasgow. The 13 deaths from scarlet fever exceeded by 4 the number returned in the preceding week, and included 8 in Glasgow and 3 in Dundee. The 4 fatal cases of diphtheria were all recorded in Glasgow; and the 4 deaths referred to diarrhœa showed a marked decline from recent weekly numbers. The deaths referred to acute diseases of the respiratory organs in the eight towns, which had been 154 and 167 in the preceding two weeks, declined again last week to 134, and were as many as 61 below the number returned in the corresponding week of last year. The causes of 68, or more than 12 per cent., of the deaths registered in the eight towns during the week were not certified.

HEALTH OF DUBLIN.

The rate of mortality in Dublin, which had increased from 33·8 to 38·7 per 1000 in the preceding four weeks, declined to 29·4 in the week ending December 24th. During the first twelve weeks of the current quarter the death-rate in the city averaged 31·5 per 1000, the mean rate during the same period being but 19·6 in London and 19·9 in Edinburgh. The 199 deaths in Dublin showed a decline of 63 from the high number in the preceding week; they included 8 which resulted from whooping-cough, 5 from "fever" (typhus, enteric, or simple), 4 from scarlet fever, 4 from diphtheria, 4 from diarrhœa, 3 from measles, and not one from small-pox. Thus the deaths referred to the principal zymotic diseases, which had been 31 and 24 in the previous two weeks, rose to 28 last week; they were equal to an annual rate of 4·1 per 1000, the rate from the same diseases being 2·7 in London and 3·0 in Edinburgh. The 8 fatal cases of whooping-cough showed a marked increase, and exceeded those recorded in any preceding week of the year. The 5 deaths referred to different forms of fever also exceeded those returned in any recent week. The fatal cases of scarlet fever and of measles, however, showed a further decline from those recorded in recent weeks. The deaths both of infants and elderly persons showed a marked decline from those returned in the preceding week. Seven inquest cases and 6 deaths from violence were registered within the city; and 69, or more than one-third, of the deaths occurred in public institutions. The causes of 31, or more than 15 per cent., of the deaths during the week were not certified.

THE SERVICES.

MEDICAL STAFF.—Deputy Surgeon-General E. H. Roberts has been appointed an administrative Medical Officer in the Bengal Presidency, vice Deputy Surgeon-General G. M. Slaughter. Surgeon-Major McNalty, having arrived in India from England, has been posted to Agra for charge of the station hospital there.

ADMIRALTY.—We understand that the Medical Director-General of the Navy, Sir John Reid, will be succeeded on Feb. 1st by Inspector-General James N. Dick, senior medical officer on the active list.

In accordance with the provisions of Her Majesty's Order in Council of April 1st, 1881, Surgeon Alexander William McLeod has been placed on the retired list of his rank (dated Dec. 9th, 1887). Staff Surgeon Valentine Duke, B.A., M.B., has been promoted to the rank of Fleet Surgeon in Her Majesty's Fleet (dated Dec. 22nd, 1887).

The following appointments have been made: Staff Surgeon John E. B. Maclean, to Plymouth Hospital; Staff Surgeon George B. Theevay, to the *Agincourt;* Surgeon Robert F. Yeo, to the *Hyacinth;* Surgeon James W. O. Underhill, to the *Duncan*, additional, for temporary service; and Surgeon John Dinnis, to the Haslar Hospital.

Correspondence.

"Audi alteram partem."

THE DISCUSSION ON COW DISEASE AT THE PATHOLOGICAL SOCIETY.

To the Editors of THE LANCET.

SIRS,—Not being aware that a paper was to be read by Professor Crookshank before the Pathological Society upon the so-called "Hendon Cow Disease," I was unable to be present at the meeting to hear the paper read or take part in the discussion upon it. I have read both with much interest in THE LANCET, and in due time may have to make some observations upon the subject. In the meantime I merely wish to refer to some remarks made by Dr. Klein during the discussion, when he is reported to have spoken as follows:—

"1. Professor Crookshank had made the initial mistake of assuming that Dr. Cameron's description of the disease was written from observations of the disease at Hendon. 2. Dr. Thin and the writer of an editorial article in THE LANCET had also assumed that Dr. Cameron had seen all he described, whereas his description of the disease was largely filled out from hearsay evidence. 3. Dr. Cameron had not, in fact, seen a case of communication to a man at Hendon; such communication from the cow to man had been observed in another locality in a former year and reported to Dr. Cameron. Dr. Klein wished particularly to insist on the fact that, though many cows were affected at Hendon, not one of the milkers had been infected. 4. In fact, the disease observed at Hendon was not that described by Dr. Cameron; there was no primary fever and no vesication," &c. &c.

With regard to the first assertion, if Dr. Klein will take the trouble to examine the paper read by me before the Epidemiological Society in April, 1886, he will see that I take special care to say that some of the earlier symptoms of the disease were not of my own observation, and this especially referred to the earlier constitutional symptoms and one or two of the local, such as sore throats. My dependence upon the observations of others for these symptoms was of necessity the case, because we arrived too late upon the scene to observe them; but I say that the description of the course of the disease after the eruption appeared upon the teats, udder, and skin is my own, and is carefully described from personal observation extended over a considerable time. With reference to the second statement, I reply that I saw and described all the local symptoms as mentioned above, and had to depend for the constitutional symptoms upon information derived from a person who seemed conversant with the disease, because the cowmen at the farm were unwilling to give any information lest it should injure themselves or their master.

These statements I took the greatest care to sift; every word referring to them was carefully weighed, because I felt that I was taking the first steps towards introducing this important question to the profession.

Since my paper was written I have obtained the evidence of the cowman who first noticed the disease amongst the cows. He milked those first affected, including the roan cow, which was the first one sent to the Brown Institution for Dr. Klein's investigations, and the red Haddenham cow from whose teat he took serum &c., and implanted it in agar-agar at the farm on Dec. 31st, 1885. The evidence of this cowman, which I will produce in due time, corroborates all my previous description of both the local and constitutional symptoms of the disease. Dr. Klein's third statement—viz., "Dr. Cameron had not observed a case of communication of the disease to a man at Hendon"—perhaps requires a word of explanation from me. If he looks at my paper, he will see that I never said so. I used the words, "A trustworthy informant received the virus of this disease into a recent scratch upon his finger," &c. This statement, which has caused so much discussion, did not seem to me, at the time, to be of very much importance. I considered the inoculation to be probably some

Digitized by Google

form of septic poisoning; but, although it did not occur at the Hendon farm, the information was derived from a trustworthy source, and I considered it worthy of record in a foot note, for future corroboration or otherwise. Whether or not any such occurrence took place amongst the cowmen at the farm, neither Dr. Klein is, nor am I, in a position to state with certainty. If it did, in all probability the fact would have been withheld from me, for the same reason that other information was, at the same time, withheld by the cowmen. I am still making inquiries in this direction, but as yet my information is of a negative character. I am greatly surprised at Dr. Klein's last statement, which is a most unwarranted one, if he has been correctly reported. From his own personal knowledge, he was not in a position to make such a statement. I assert, as I have already done, that my description of the cow disease is carefully given from personal observation at the farm, and from notes taken at the time. My observations and statements have since been corroborated by those in charge of the animals; and until they are refuted by more extended observation, I hold them to be, in nearly all particulars, substantially correct.

I am, Sirs, yours very truly,

Hendon, Dec. 26th, 1887. JAMES CAMERON, M.D.

To the Editors of THE LANCET.

SIRS,—I shall be obliged by your correcting in your next issue a statement which I am reported to have made at the special meeting of the Pathological Society. Your report (Dec. 24th) makes me say: "There was no fever (in the Hendon cows), no primary eruption, and no vesiculation." I did not make any such statement; I did not say anything about the absence of a primary eruption and about vesiculation. I am, Sirs, your obedient servant,

E. KLEIN.

The Brown Institution, Wandsworth-road, S.W., Dec. 26th, 1887.

MYXŒDEMA.

To the Editors of THE LANCET.

SIRS,—In THE LANCET'S report of the Medical Society's meeting on Nov. 28th is a case of myxœdema in a man brought forward by Dr. Savill, who spoke of the rarity of this disease in the male, only nineteen cases being published. I have now under observation an extremely well-marked case in a man aged sixty-seven, who has the usual placid, though somewhat sad, countenance, muddy complexion, harsh skin, scanty hair, waddling gait, slow utterance, and chilly feeling peculiar to this disease. Evidence certainly points to the much greater frequency of myxœdema in the female, notwithstanding the opinion formerly expressed by Sir Andrew Clark, who considered it more often met with in the male. I have had under my care during the last six years ten cases of myxœdema, and eight of these were women. Another point of interest in Dr. Savill's case is "the profuse hæmorrhage, probably from the prostate gland." Have we yet obtained sufficient evidence to place hæmorrhage amongst the symptoms of myxœdema? About a year ago I was surprised to find profuse and repeated hæmorrhage follow the extraction of two teeth in patients with myxœdema within three weeks of each other, and, thinking this more than a coincidence, I searched authorities on this disease for mention of hæmorrhage, but found none, except a remark of Sir Andrew Clark's that menorrhagia was very common. I then referred to all the cases published, from Sir William Gull's first case onwards, and found thirteen cases where hæmorrhage of one form or another had occurred, but had not, as a rule, attracted any particular attention as bearing on the disease (except in a case of Dr. James Anderson's, where the hæmorrhage was assigned as a cause). However, on grouping these cases together the fact at once assumed importance. I therefore reported my two cases and the quotations from the other thirteen in an article, "Hæmorrhagic Tendency in Myxœdema," in THE LANCET of April 2nd. In that article I ventured to hint that with more evidence the hæmorrhagic tendency might become established as a special feature in myxœdema. Dr. Savill (whose case adds one more to the list) helps to confirm this by the remark that hæmorrhage might now be regarded as one of the symptoms of the disease.

I am, Sirs, yours faithfully,

Mitcham, Dec. 1887. OSCAR B. SHELSWELL.

"THE CORK POISONING CASE."

To the Editors of THE LANCET.

SIRS,—In your leading article on the above case in week's issue, in which you were good enough to favourable mention of my evidence, you remark th would have been more comfortable for myself to hav the assistance of another analyst. This I quite admi at the same time desire to point out that I consider th gestion of procuring the aid of a second analyst in s case should in the first instance emanate from the as in this case, had such an application been made by might possibly be inferred that I did not feel myself petent to undertake the duties entrusted to me. Yo mention in your article that "it would appear to be th occasion on which Dr. Pearson has been required to post-mortem inspection, and to chemically examine th cera in a case of arsenical poisoning." This is quit so far as the human subject is concerned, but it m right to mention that I have on very numerous occ made analyses of the viscera of some of the lower a after death from arsenical and various other poisons. facts were not brought out either in my direct evi or in re-examination; they could not well be volun and were naturally avoided in cross-examination; in counsel for the defence endeavoured to make it appe there was something essentially different in the m used in extracting poisons from human remains from usually employed for their separation from other o materials. Had a medical expert been examined for t fence this matter would probably have been cleared refrain from alluding to the numerous medico-l points of interest, as I purpose to discuss them a length in connexion with a report of the medical per this most important case at no very distant date.

I am, Sirs, yours faithfully,

Cork, Dec. 27th, 1887. C. YELVERTON PEAR

ANTIPYRIN IN HEADACHE.

To the Editors of THE LANCET.

SIRS,—I firmly believe that chemistry, hae, in the drug, found a most invaluable remedy for migraine an forms of headache that seem to be due to worry and work. In those cases where I have tried it, its eff simply been marvellous. In one case of a lady w years has been the subject of most distressing pe attacks of intense pain referred to the occiput, that all ordinary remedies, this drug relieved at once, this case the depressing fear of impending attacks is thing of the past. I presume in these cases it ac powerful sedative to the nervous system, and happily no ill effects whatever—a great desideratum. Ten repeated every hour for two or three hours, is my giving it, and then at intervals of six hours for a two after, to prevent all chance of a recurrenc generally being at the desire of the sufferer.

I am, Sirs, yours faithfully

Sherborne, Dec. 24th, 1887. NATHANIEL EDWD. DA

THE TREATMENT OF CANCER.

To the Editors of THE LANCET.

SIRS,—With a certain reservation I accept the st which Mr. Pemberton uses the term "cure." He d regard Dr. Smith's case[1] as cured, *because* the dise curred after an immunity of nineteen years, though, ing to Mr. Pemberton's own views, had Dr. Smith's died a year ago from "causes common to the bre from ordinary wear and tear of natural structures," would have regarded the patient "cured" of cancer Whilst admitting that speedy recurrence of the dise operation precludes the application of the term "c the treatment adopted, yet if a lengthy period have before the recurrence appears at the original site it i assume that the second outbreak should be consi wholly distinct from the first, the proclivity of ma disease to develop *de novo* in s[illegible] tissue favouring lief. If Mr. Pemberton perus[illegible] a paper from the

[1] THE LANCET, 188[illegible] vol. II., p. 3[illegible].

Digitized by Google

Mr. Treves,[2] which has been adverted to in one of your recent leading articles, he will find evidence showing that malignant disease has been cured by arsenic. When a cancerous growth is removed by the knife no surgeon can positively predict freedom from recurrence; but if malignant growths resolve after a course of Chian turpentine, arsenic, or other remedies, the prognosis is most hopeful. Whilst thanking Mr. Pemberton for his courteous response to my inquiries, I would remark that I never asked him in what sense he spoke of cancer "infiltrating textures around its origin," but how that sense differed from cancer as defined by myself in your issue of the 3rd inst.[3] Neither did I ask how "adjacent glandular contamination" is recognised, but how Mr. Pemberton recognises clinically the *commencement* of that process.—I am, Sirs, yours faithfully,

Dec. 24th, 1887. CHAS. E. JENNINGS.

ARMY MEDICAL DUTIES AND ARMY MEDICAL DEATHS.

(From a Correspondent.)

THE Medical Department is fiddling while Rome is burning—analysing its own opinions on the theory of rank, while, in the words of Sir Thomas Crawford, "nearly one-half of the whole number have, during the past thirty years, been sacrificed in the public service" (4616), and while those who live by the breath of party politics are seeking to support the election cry of economy by preferring the half hour's arithmetic of an official actuary to the lifelong experience of the Director-General. Mr. H. Fowler asks: "Mr. Knox said that he thought the time would arrive, and before long, when the non-effective would be in excess of the effective pay." The Director-General replies: "Mr. Knox is a very high authority upon financial matters, but I am bound to say that I disagree with him" (4676). Thus sways the struggle of promised retrenchment against human life, and elicits from Dr. Cameron a query with regard to a statement that the rate of mortality amongst medical officers in the army is 27 per 1000. To which Sir Thomas Crawford responds: "I dare say that would be correct" (4826). "There is no branch in the whole of the public service in which the mortality is so great as it is in the medical department of the army" (4617). Still further may it be asserted that there is no trade in the whole list of English industries which, in the percentage of its victims, can equal medical service in the army. The recent statistics of Dr. Ogle upon the effect of occupation upon the life of males between twenty-five and sixty-five years of age demonstrate that the miner may labour without light, the knife-grinder may inhale the flying particles of steel, the earthenware manufacturer may breathe the dust of clay, and the publican indulge to the utmost the temptations of his calling, and yet none can equal in loss of life the medical officers of the army. Yet the only answer of the Royal Commission before whom this fact was brought to light is Mr. Stanhope's question: "Could not the medical officers be kept longer than that in the army with advantage to the public service?" Could they not be held still longer at the occupation which is killing them at a rate at which no other class of Englishmen dies? By Factory Acts and Parliamentary interference the life average of every other British subject has been lengthened, yet the same Parliament demands that when economy requires the medical officer must die. Is it not, then, the duty of the Parliamentary representatives of the profession, in precedence of all other questions, to press upon the House of Commons the demand of humanity that some investigation shall be made into the cause of this mortality, which exceeds not only that of all other public servants, but even that of the deadliest English trades? or must those who have no votes be left to perish, and the philanthropy of the closing nineteenth century confess that human life is valued only in connexion with the ballot box?

[2] A Form of Glandular Swelling that is cured by Arsenic: Clinical Soc. Trans., vol. xx., p. 176, et seq. [3] THE LANCET, p. 1142.

MR. W. M. VORES, M.B. Cantab., M.R.C.S., of Yarmouth, whilst driving, was thrown from his carriage, sustaining, we regret to learn, an injury to one of his arms.

BIRMINGHAM.

(From our own Correspondent.)

THE USE OF THE REVOLVER.

THE use of the revolver appears to be becoming more prevalent as an aggressive weapon, in spite of the monitions of judges and the examples made of those who thus practise on their fellow citizens. The recklessness which often accompanies lawlessness could hardly find a more dangerous instrument of offence. Though hitherto its use has been looked upon as foreign to our native mode of settling quarrels, it is to be feared that this fortunate belief is likely to be abolished. Two instances have occurred in this town within a few days, one in which a policeman was deliberately fired at twice, one shot wounding him in the lower jaw. Another in which a girl was wounded by shots fired at some men from whom a supposed grievance had been received. The habit of carrying revolvers is doubtless a pernicious one; it reminds us of the observation made by old obstetric writers: If you carry forceps in your pocket to a midwifery case, it very much increases the temptation to use them.

CHRISTMAS AT THE HOSPITALS.

The spirit of charity which is usually associated with this festive season finds choice ground in the attempt to make cheerful and lighten the sufferings of the inmates of these institutions. At most of these places the interior of the building has been prettily and tastefully decorated, and much time and care have been given to make the effect pleasing and agreeable to the sufferers. In addition there has been Christmas fare to all who could partake of it in a form suitable to their condition. The children have enjoyed the pleasures of Christmas trees and presents, the attendants here have their own parties and friends, while the officers have disported themselves in a manner which has left no occasion for thinking that their duties are not mixed with some degree of mirth calculated to lighten their labours and their cares.

ANTI-VARIOLE LEAGUE.

A combination of persons under this somewhat formidable title have lately been endeavouring to show the baneful results arising from vaccination, and have freely disseminated literature for the purpose of proving their position. The testimony of expert observers and the common sense of the thinking portion of the public will not be misled by the enthusiasm of extremists in this particular direction. At the same time it is necessary that accurate information should be at hand to refute the allegations of opponents to a useful and beneficent law. Argument of a definite kind should be in the possession of all medical men, and the aggression should be reasoned fairly without attempting to take refuge in the assumption of authority only. It is too often the custom to think that the question is not worth reasoning or investigating further, but in the present day people think for themselves, and often intelligently so, on medical matters. Conviction therefore is much more likely to follow from judicious exposition of knowledge than by the bare denial of statements made by those who, without reasoning, feel strongly.

NORTHERN COUNTIES NOTES.

(From our own Correspondent.)

THE HEALTH OF NEWCASTLE-UPON-TYNE.

IN the course of this correspondence, now I believe extending considerably over twenty years, errors and mistakes will sometimes naturally occur. These, however, thanks to the facilities afforded me by THE LANCET, I am always enabled to correct and acknowledge. With regard to the health of this city and the "notes" thereon, which have called forth the spirited but not discourteous letter last week from our able and indefatigable medical officer of health, Mr. H. E. Armstrong, I cannot see by his showing that I am wrong in the opinions I have expressed, and which are shared by many others here. Certainly the allegations I made involve wilful and often ignorant

Digitized by Google

omission on the part of many householders. In proof of which I may state that at an institution in this city with which I am connected, I frequently see patients suffering from the sequelæ of infectious diseases, for which they have had no medical attendance. And why? Because they fear the trouble notification may bring upon them, and some of them believe that the inspectors may be the carriers of worse infection than that which they are sent to inspect. I would ask our medical officer of health, May not they be right in this fear? And if not, why not? Is there anything protective in the uniform of the officials or their carbolic odour? I would gladly let our medical officer of health see the practice of this institution—in his private capacity, however, for which I have the highest respect; for I believe it very wrong, and, to my feelings, an infringement of the rights of hospitality, to allow anything in the way of *espionage* to be practised, and of course it would ruin the popularity of the hospital. I may say that I always certify infectious cases coming under my notice in private practice, which are very few, however, owing to causes which I need not specify here. I do so because it is the "law of the land" as regards this city, and also because I believe the information given may be of some service for statistical purposes. I am not very much surprised that the evils spoken of in my "Notes," and described as "fantastic" by our medical officer of health, have not come under his experience. With his multifarious duties he cannot be expected to know everything, and for many reasons he will be the last person to be cognisant of many matters affecting the health of the city; he will just know what his inspectors tell him. But when they get more experience and their powers of observation extended, they will tell him that the dissipation at the "long bars," improper feeding, clothing, and housing are important factors in the generally high death-rate which is causing our citizens so much concern. It is the candid opinion of many qualified to judge that a proper inspection of our new streets and houses, with their surroundings, before occupation, would do much to reduce this persistent high death-rate.

THE DEATH-RATE OF NEWCASTLE AND SCHOOL CHILDREN.

The sub-committee of the Board School have presented a report with regard to the high death-rate from Nov. 25th, 1886, to Nov. 25th, 1887. The number of deaths amongst scholars at the Board Schools was 34, with an average of 1000 on the books. This was rather less than 3·4 per 1000 for the year. The number of deaths from zymotic diseases was 13, or 1·3 per 1000. The statistics showed clearly that the high death-rate was not owing to the deaths of children. It was equally clear that it did not result from pressure put by the officers on the parents to send their children to school before they had fully recovered from infectious diseases.

THE UNIVERSITY OF DURHAM AND ITS DEGREES.

From all sides I hear complaints as to the late action of the University of Durham, and its opposition to the amalgamation of the London Colleges, and some spirited letters have appeared in our papers against the narrow policy of the University in this matter; but I suppose the University and its connexions mean to "hold the field" if they can, though no one will for one moment believe that a University should be allowed to stop the progress of a great medical reform.

Newcastle-on-Tyne, December 27th.

DUBLIN.

(From our own Correspondent.)

THE EPIDEMIC OF MEASLES AT CAPE CLEAR.

THE outbreak of measles at Hare Island and Cape Clear has assumed considerable proportions, and it is estimated that one-fifth of the population of the latter place are prostrated by the disease. It is satisfactory to learn, however, by recent returns, that there are no dangerous symptoms connected with the new cases, and that the disease seems less virulent, the mortality being much less than heretofore. At a meeting of the Skibbereen guardians last week Dr. O'Farrell, Local Government Board inspector, who had recently visited the island, gave a very graphic report of the prevalence of the epidemic, and adduced cases showing the malignant nature of the disease. In one case a fisherman only survived eight hours after being attacked, and some families had lost several adult members within a few days. Dr. O'Farrell suggested that a temporary hospital should be established on the island with a trained staff of nurses to attend the sick, which has been carried out, and a medical practitioner will reside there for the present, while plenty of beds, bedding, and medical comforts have been sent to the islanders.

DUBLIN HOSPITAL SUNDAY FUND.

The returns from nearly forty churches have not yet been received, but so far as can be judged it is expected that there will be a decided falling off in the total collected for the fund this year.

MERCER'S HOSPITAL, DUBLIN.

It is stated that the expenses connected with the recent litigation have amounted to upwards of £1500.

Dublin, Dec. 26th.

PARIS.

(From our Paris Correspondent.)

TINEA DECALVANS.

IN the debate opened by Dr. Ollivier, at the Academy of Medicine, on Tinea Decalvans as it occurs among school children, and which was reported in THE LANCET of December 17th, Professor Hardy, in response to the remark made by Drs. Ollivier and Cornil, as to the non-contagiousness or parasitic nature of the malady in question, could not admit that the non-discovery of the micro-organism of tinea decalvans was any proof in favour of their theory, as there are other affections in which no micro-organism or microbe has ever been seen, and yet no one could doubt their being contagious—such, for instance, as measles, scarlatina, and many others. Under the circumstances, and until proof to the contrary is adduced, Professor Hardy thought that the benefit of the doubt which exists should be accorded to the pupils in health by separating them from those who are affected with the disease. In taking up the debate at the meeting of the Academy last week, Dr. Hardy recalled, in support of his argument, that in 1875, after an epidemic of tinea decalvans that occurred at the Lycée of Vanves, it was decided by a commission that the pupils affected with the disease should be sent to their homes. Since that period, as the example was followed by other schools, the disease became much less frequent in these institutions. Dr. Hardy further observed that tinea decalvans is certainly not fatally contagious. To develop itself, the disease requires certain conditions, and of greater part of these conditions we know nothing. We know only that the disease affects particularly young subjects, debilitated and nervous persons, and those who have been under the influence of great sorrow. The Professor then cited a great number of facts, in which are found incontestable proofs of the contagiousness of the malady. Thus, when the 122nd Regiment of Infantry was stationed at Montpellier, it was joined by two recruits, last spring, who were affected with tinea decalvans. In the month of December following, there were more than eighty men affected with the disease. Dr. Coustan, surgeon-major of the regiment, who has published a very interesting report on this epidemic, considered the scissors with which the soldiers' hair is cut to have been the cause of the propagation of the malady. Measures were taken to remedy this evil, and the epidemic disappeared. At the Saint-Louis, the well-known hospital for skin diseases, it has been observed that the medical men and students attached to the hospital are much more frequently affected with tinea decalvans than medical men and students at any of the other hospitals. Bazin admitted two sorts of this affection: the one parasitic, the other due to a simple perturbation of the nervous system. This, Dr. Hardy said, was possible, but as they followed the same course and had the same symptoms, and as, in fact, they cannot be distinguished the one from the other, the pupils affected with the disease must be kept away from the schools. Dr. Hardy's discourse was frequently applauded, and although Dr. Ollivier was somewhat shaken

Digitized by Google

in his opinion by it, yet he did not seem wholly convinced, and promised to enter more fully into the subject at the next meeting.

M. FERRY'S ASSAILANT.

The mental state of Aubertin, the would-be assassin of M. Jules Ferry, who it will be remembered fired three shots at the latter with a revolver on the 9th of this month, is quite a psychological puzzle to the alienists who have been charged to examine him; for he is at times so violent that they are obliged to have recourse to the strait-waistcoat, and at other times he is perfectly sane and quiet. In the morning he would appear to be dying, in the evening he would eat with a good appetite; at noon he would be occupied with the Muses, at four o'clock in the afternoon he would try to break his skull by knocking it against the wall. It may be remembered that on being arrested he declared himself not to be mad, but soon after his incarceration symptoms of insanity set in. On a recent visit of the officials the man declared that he perfectly recollected the scene of the 9th of December, but could not explain the motives which prompted him to commit such an act of insanity. He did not remember the insane acts he had committed since his incarceration. He believes that he has simply recovered from a long syncope. The medical men who have visited him say that they were not at all surprised at the apparent improvement that took place in the man's condition, as this frequently occurs after such violent crises. A terrible relapse is prognosticated.

Paris, Dec. 27th.

Obituary.

GEORGE SYLVESTER, M.R.C.S.

ON Dec. 26th there passed to his rest George Sylvester of Trowbridge, Wilts, the senior member of the Royal College of Surgeons of England, and, we believe, the oldest member of the medical profession. Born on March 10th, 1788, he qualified as M.R.C.S. in 1810, and so was close upon his hundredth birthday. The deceased gentleman was in early life an assistant-surgeon in the Royal Navy, and saw some active service in eastern seas, for which he received a medal. After his retirement from the service he settled in Trowbridge, and perhaps at one period of his career could boast of the largest midwifery practice in Wilts. He was one of Her Majesty's coroners for Wilts during the long period of thirty-four years. Mr. Sylvester was most precise in his habits, and a diligent student even after ninety years of age. Until the last two or three years he was a regular attendant at church, and a very keen politician. He was a wonderfully hale old gentleman, owing much of his health to his remarkably methodical habits, and it is needless to say that he enjoyed the respect of his medical brethren in no small degree. Of his four sons, one succeeded him in practice, another in the coronership. Two of his grandsons are surgeons. A third is a senior student at St. Bartholomew's Hospital; and a fourth is now about to enter. The deceased is, we believe, succeeded in his honours of seniority by his cousin, Dr. Charles Sylvester, of Bath, who qualified in 1816.—*From the pen of one of another medical family, who, for three generations, have practised side by side with the Sylvesters.*

CENTENARIANS.—Information has been received at Rochester, his native city, that Mr. Louis Lewis, of Sandhurst, New Zealand, who attained his 104th year on Sept. 24th, is still in the enjoyment of good health, and retains all his faculties.—Mr. Robert Yorston of Kirkwall attained his 101st birthday on the 17th inst.—Mrs. Mary Brown died at her residence in Grantham on the 27th inst., aged 100 years. The whole of her faculties are reported to have remained perfect to the end, her eyesight being especially good.

SEVERAL tradesmen of Ormskirk have decided, instead of giving Christmas-boxes this year, to subscribe towards the erection of a cottage hospital in the town, for the reception of accident cases, several instances having proved the great need of such an institution.

Medical News.

UNIVERSITY OF LONDON.—At the recent B.S. Examination for Honours the following satisfied the examiners:

Surgery.

FIRST CLASS.

Roughton, H. W., M.D. (Scholarship and Gold Medal), St. Bartholomew's Hospital.
Tubby, Alfred Herbert (Gold Medal), Guy's Hospital.
*Carless, Albert, King's College.
Braddon, William Leonard, Guy's Hospital.
Brown, Herbert Henry, University College.

SECOND CLASS.

Eq. { Holder, Sydney Ernest, University College.
Wynter, W. Essex, St. Barthol. and Middlesex Hospitals.
Clarke, William Frederick, Guy's Hospital.
Flemming, Percy, University College.

* Obtained the number of marks qualifying for a Gold Medal.

UNIVERSITY OF OXFORD.—At a congregation held on the 17th inst., the following degrees were conferred:—

DOCTOR IN MEDICINE.—Christopher Childs, Merton.

BACHELOR OF MEDICINE.—Francis S. Hawkins, Oriel.

UNIVERSITY OF CAMBRIDGE.—At a congregation held on the 15th inst. the degree of Doctor of Medicine was conferred on

Thomas George Styan, Trinity.

On the following day the Special Board for Medicine was authorised to watch the proceedings before the Privy Council in the matter of a petition from the Royal College of Physicians of London and the Royal College of Surgeons of England for a Charter and power to grant degrees, and, if necessary, to prepare a petition to the Privy Council.

THE Earl of Derby has contributed £1000 to the funds for the rebuilding of St. Mary's Hospital, Manchester.

MARGARINE.—The Act for the Better Prevention of the Fraudulent Sale of Margarine, passed last session, comes into operation on the 1st of January, 1888.

SUPERANNUATION ALLOWANCE.—Mr. Alexander W. McLeod, late medical officer for the First District of the Fulham Union, has been granted a superannuation allowance of £35 per annum.

SEVERAL contributions have been received at the Mansion House in response to an appeal by the Lord Mayor for £20,000, to enable work to be provided for 1300 of the unemployed in making gardens and pleasure grounds in various districts of the metropolis.

MEASLES AT INGHAM.—Measles is very prevalent at Ingham in Lincolnshire, the attacks having numbered from 120 to 150. The neighbouring village of Fillingham is also invaded. A large number of adults have been attacked, but as yet without fatal result.

TRIPLETS. — The wife of a labourer, residing at Wright's-cottages, East Acton Brick-fields, was delivered by Dr. Good of Shepherd's-bush, on the 18th inst., of three children, a boy and two girls. Mother and children are doing well.

PRINCESS CHRISTIAN has consented to act as President of the Executive Committee of the British Nurses' Association. The aim of the Association is to unite and organise, under the control and with the assistance of the leaders of the medical profession, all women engaged in nursing the sick.

SMALL-POX IN PARIS.—An outbreak of small-pox is reported from Paris. Beginning among the German colony at Pantin, the disease has now spread to Aubervilliers. The source of the epidemic has been traced to the outer boulevards fair, which the municipality has allowed to become a permanent institution.

MEDICO-PSYCHOLOGICAL ASSOCIATION.—The following gentlemen passed the examination for the Certificate in Psychological Medicine, granted by the Medico-Psychological Association, at Edinburgh, on the 23rd and 24th inst.:—Frank Lang Collie, M.B. and C.M. Aber.; William Gemmell; Andrew Rowand, M.A., M.B., and C.M. Edin.; Arnold E. Thorpe, L.R.C.P. and L.R.C.S. Edin.

Digitized by Google

LONDON TEMPERANCE HOSPITAL.—By the donation of £6000 from a benevolent friend of this charity, its pressure of debt, by which a number of wards were kept unoccupied, has been removed. Other hospital authorities would be glad to experience so happy a termination of their pecuniary difficulties.

A WEDDING PARTY POISONED.—At Great Houghton, a suburb of Northampton, a wedding party has been poisoned by partaking of tea brewed in an old copper urn. All the guests, twenty-two in number, were seriously affected by verdigris, and it was only by prompt medical assistance that fatal effects were averted.

AYR COUNTY HOSPITAL.—The annual general meeting of the supporters of this institution was held on the 12th inst., when it was reported that the number of in-patients treated during the past year was 436, and of out-patients 1334—an increase on the preceding year of 30 and 51 respectively. The income had amounted to £1851, and the expenditure to £1504.

DEATH OF DR. TOLEKEN, OF MONKSTOWN.—The death of Dr. Toleken, ex-Fellow of Trinity College, occurred at his residence in Monkstown on the 14th inst. Dr. Toleken graduated in 1825, and became a Fellow in 1836, taking the degree of M.D. in 1841. Some years ago he resigned his fellowship.

ROYAL SURREY COUNTY HOSPITAL.—The new wing at this institution was formally opened on the 19th inst. The addition contains two wards, each sixty-three feet long by eighteen wide and fifteen high, and affording accommodation in each for fifteen patients. The estimated cost of the extension, including furnishing, is £6600, and more than sufficient to cover this expenditure has been subscribed during the two years the work has been in progress.

Births, Marriages, and Deaths.

BIRTHS.

BEECH.—On the 24th inst., at Fawkham, Kent, the wife of Surgeon-Major Lionel Beech, Indian Medical Department, of a son.

BELL.—On the 23rd inst., at Louth, Lincolnshire, the wife of Chas. W. J. Bell, M.R.C.S., of a daughter.

Notes, Short Comments, & Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

All communications relating to the editorial business of the journal must be addressed "To the Editors."

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news-paragraphs should be marked and addressed to the Sub-Editor.

Letters relating to the publication, sale, and advertising departments of THE LANCET *to be addressed "to the Publisher."*

We cannot undertake to return MSS. not used.

THE CHILDREN OF THE POOR.

MR. HENRY MANNERS, Sanitary Inspector to Watford Local Board, has called the Prime Minister's attention to the practice of tramps bringing out into the streets half-starved and badly-clothed children to assist in procuring their precarious livelihood. The more inclement the weather the more children are seen out, no doubt from the knowledge vagrants have of the fact that compassion runs higher by these exhibitions of extreme misery. It is well known that these unfortunate little ones are hired for begging purposes, and Mr. Manners suggests that the Government should get a short Bill passed, making it penal for children under a certain age to be with tramps in the streets, taking part in singing or other musical exhibitions. Lord Salisbury, in his reply, promised to bring the subject under the notice of the Local Government Board.

Surgeon-Major MacLaren.—The data supplied are scarcely sufficient to form a groundwork for satisfactory comment on the case.

Dr. Jas. Barr.—Very shortly.

EPSOM COLLEGE.

To the Editors of THE LANCET.

SIRS,—I make it a rule never to reply to anonymous correspondents; but as in your issue of Dec. 24th "A General Medical Practitioner" is apparently prepared to sacrifice the opportunity of securing for his sons a first-rate education at a minimum of cost, I write to suggest that he should apply to the head master of Epsom College, or to the secretary at 37, Soho-square, who will give him reliable information both as to the course of education pursued in the College and the cost.

I am, Sirs, yours faithfully,

C. HOLMAN, M.D.,
Reigate, Dec. 26th, 1887. Treasurer of Epsom College.

To the Editors of THE LANCET.

SIRS,—If "A General Medical Practitioner," writing in your issue of to-day on the subject of Epsom College, will kindly apply to me for information, I have no doubt that I shall be able to convince him that there is no school at the present time more economically and, I hope, more efficiently managed, nor one that offers more advantages for those who are intending to enter the medical profession.

I am, Sirs, yours faithfully,

W. CECIL WOOD, M.A.,
The College, Epsom, Dec. 24th, 1887. Master of Epsom College.

SUGAR AND TEA.

To the Editors of THE LANCET.

SIRS,—The excessive use of sugar in any of its forms is a predisposing cause of catarrh of mucous membranes and of eczema, and the recommendation to cease their use altogether or nearly so facilitates the cure of these diseases. I can, or think I can, support the foregoing proposition as to catarrh of the air-passages from personal experience, and as to both from observation. To avoid catarrh, rather than to relieve the actual disease, in the case of the Crown Prince may be the motive for prohibiting or restricting the use of sugar in His Imperial Highness's dietary. Regarding the drug called tea, which we all use so much of now-a-days, I will only say that, greatly as the drinking of the infusion (sometimes decoction) of Indian teas is to be desired to promote the prosperity of "our great dependency," I firmly believe that they are more conducive to constipation and nervous weakness than the old mixture of Chinese teas. The place of Indian teas is to give "body" as an adjunct to those of China. Tea is a useful drug to us, just as coca is to South Americans. But the use of both is abused; and it is a pity, I think, that fashion—more potent in this matter than even the medical press—does not exercise its powers in checking the too great use of these sister ingredients of daily fare.

I am, Sirs, yours obediently,

Liverpool, Dec. 26th, 1887. ARCHIBALD D. MACDONALD, M.D. Edin.

"A WARNING."

To the Editors of THE LANCET.

SIRS,—Will you allow me through your journal to caution medical men against a man playing them a trick, to which I fell a victim on the 19th inst. He called upon me that evening, saying he was living in the town, but gave me a fictitious address, and perhaps a false name (John Smith), that he was a carpenter by trade, that his truss had broken and he wanted another for which he would pay by instalments. Before he left he asked for a note for his club, as he could not work without a truss. I gave him a printed form like I use for my own club patients, and this, it appears, he immediately used in this town for begging purposes. I need not say he has failed to appear and claim his truss, and the police up to now have not been able to find him. I write to warn people against him. Should anyone come across him, Superintendent Childs, of this town, would be glad to be informed of his whereabouts.

I am, Sirs, yours truly,

Bridgnorth, Dec. 27th, 1887. W. THURSFIELD, M.D.

RESIDENCE FOR AN ASTHMATIC PATIENT.

To the Editors of THE LANCET.

SIRS,—I shall be extremely obliged if any of your readers will favour me with an opinion as to the suitability of Genoa or Florence as a residence for an asthmatic patient. The person in question, a girl aged about twenty, is of a gouty family, but with no phthisical history. She finds high and dry places very suitable as residences.

I am, Sirs, yours faithfully,

Dec. 20th, 1887. H. A. L.

THE VALUE OF PARAFFIN AS A HAIR RESTORER.

To the Editors of THE LANCET.

SIRS,—Perhaps some of your correspondents may be in a position to answer the following questions.

1. Is ordinary paraffin oil of any use as a hair restorer? 2. Is its use as such likely to be followed by any evil effects? 3. What is the best method of disguising its smell?

I am, Sirs, yours faithfully,

Dec. 21st, 1887. J. G.

IN consequence of the necessarily increased extent of the Index for the current volume, and the length to which our Annual Retrospect has run, we are reluctantly compelled to postpone the appearance until next week of several articles and communications of interest to the profession. Many advertisements have also for the same reason been omitted from the present issue.

Dr. Edward Jones.—There are several. The best are valve closets, which are somewhat expensive. A cheap and clean apparatus, which is not a valve, is made by Dent and Hellyer of Newcastle-street, Strand, called the "Hygienic."

S. W. has not enclosed his card. We do not reply to anonymous communications.

COMMUNICATIONS not noticed in our present number will receive attention in our next.

COMMUNICATIONS, LETTERS, &c., have been received from—Dr. C. Y. Pearson, Cork; Dr. G. Johnson, London; Mr. Christopher Heath, London; Mr. Jalland, York; Dr. Sturges, London; Dr. A. Hamilton, Windermere; Sir Coutts Lindsay, London; Dr. A. D. Macdonald, Liverpool; Dr. Holman, Reigate; Mr. Hopkins, London; Mr. W. C. Wood, Epsom; Dr. Thursfield, Bridgnorth; Dr. Rumboll; Dr. Savage, London; Dr. E. Haydon, London; Mr. Barwell, London; Mr. F. W. Joshua, Great Malvern; Herr R. Danhardt, Eisenach; Dr. Sansom, London; Mr. McKeown, Manchester; Dr. W. Russell, Edinburgh; Mr. Thos. Pardup, Manchester; Dr. Mallins, Watton; Dr. Theodore Williams, London; Mr. T. G. Paterson, Alexandria; Messrs. Dewar and Sons, Perth; Dr. Hime, Bradford; Mr. Faulkner; Mr. Berkeley Hill, London; Dr. Saul, Lancaster; Mr. Stirartian; Messrs. Dawson Bros., Montreal; Mr. Tetley, Keighley; Dr. N. H. Davies, Sherborne; Dr. Jacobsen, Havana; Mr. P. Swain, Plymouth; Mr. C. Jennings, London; Mr. Hawkins, Birmingham; Mr. Tilley, Queensland; Dr. Gooding, Barbadoes; Dr. Jas. Cameron, Hendon; Prof. G. Ria, Naples; Mr. Michelli, London; Dr. W. J. Collins, London; Mr. H. Kornfeld, Berlin; Mr. W. H. Borham, Fulham; Dr. Highmoor, Tadcaster; Mr. Freeman, Reading; Mr. Curran, Kensington; Mr. Fry, Wilts; Mr. Petter, Yeovil; Mr. Grimsley, St. Asaph; Mr. Lane, Kensington; Dr. Popham, Wellington; Mr. Burnet, London; Mr. Salter, Chard; Mr. Palmer, Peterton; Mr. Bishop, London; Dr. Hensman, Kensington; Mr. Warren, Bristol; Mr. Spence; Mr. R. H. Parker, London; Mr. H. Page, London; G. G.; Cymro; Rustic; Country General Practitioner; G. B.; Villiers; A Resident; Fides; Medicus, Manchester; K. C.

LETTERS, *each with enclosure*, are also acknowledged from—Dr. Benthall, Southsea; Mr. Tsowart, Sheffield; Mr. Burd, Shrewsbury; Mr. Smith, Aberdeen; Mr. Simpkin, Lagos; Messrs. Gwin; Messrs. Harris and Co., Birmingham; Mr. W. Smith, London; Mr. Manley; Messrs. Lee and Martin, Birmingham; Mr. Robinson, Harrogate; Mr. V. de Laprade, Lyons; Mr. Valentine, Somerset; Mr. Harper, Colombo; Mr. Fuge, Taunton; Mr. Potter, Kensington; Mr. Beckett, Eastbourne; Mr. Fernandez, Devon; Mr. Ward, London; Mr. Flemming, Wilts; Dr. Emanuel, Malta; Mrs. Manley, Croydon; Messrs. Leader, Sheffield; Dr. Cochrane, Bradford; Dr. Parker, Clifton; Mr. Hello, Nottingham; Mr. Crickmay, Lochfield; Mr. Heywood; Mr. Sampson, York; Mr. Lawrence; Mr. Stroner; Mr. Briggs; Mr. H. Johnsen, Copenhagen; Mr. F. Wyatt; Dr. Blum, Munich; Mr. Kennard; Medicus, Hereford; Harvey; Medicus, Plaistow; Oxonian; Alpha, Dublin; Iota, London; Monitas, London; Z. A., Stamford-hill; A. D., Cowes; J. B.; Leamington; J.; Lux; X., Sheffield; X.Y.; Medicus, Northwich; Scapula; Spes; M.D.; Surgeon; P.H.

Leicester Daily Mercury, Southern Times, Melbourne Herald, Western Mail Bournemouth Observer, &c., have been received.

——, Sir J., on vaccination, 772
Horses, a plea for, 77; guttural pouches of, 812
Hosford, Dr. B., on pain in the heels, 693
Hospital appointments, monopoly in, 329
—— management, 28
—— reform, theories of, 1032
—— Saturday fund, 45, 83, 230, 1149, 1199, 1286
—— staff, partners on a, 1132
—— Sunday fund, 22, 87, 190, 224, 236, 274, 1075, 827, 1225, 1231; collection for 1887, 122, 1127, 1138; meeting of constituents of the, 1303; in Birmingham, 137
Hospitals, complaints against, 274, 771; abuse of, by the well-off, 947; large legacies to, 978; fires in, 1034; and dispensaries, relations of, 1035; telephones in, 1301
—— Association, the, 791, 892
House, an unhealthy, 334
—— of Commons, ventilation in the, 143, 294
Howard Association, 94; report of the, 671
Hubert, Mr. A. E., on the "Doecker" portable hospital, 743
Huddersfield district, health of, 1141
Hughes, Mr. A. W., on the central nervous system and axial skeleton in anencephalous monsters, 1212
—— v. Langmore, 683
Hull urban district, health of, 435
Human locomotion, 1030
Hume, Mr. T., a medical biographical dictionary, 297
Humerus, post-acromial dislocation of, 167; permanently displaced head of, 372
Humphreys, Mr. F. R., on inversion of the uterus, 49; on the treatment of coma in young children by hypodermic injection, 1109
Hunt, Dr. J. P., on hay fever, 137; corrigenda, 199; the Army Medical Department, 345
——, Dr. J. W., case of cerebral syphilis, 1115
——, Mr. J. M., on alarming syncope from syringing the ear, 756
——, Mr. T. S., a New Basis for Chemistry (review), 419
Hunterian Museum, additions to the, 126
Hunter's canal, aneurysm of the superficial femoral artery in, preceded by aneurysm of the common femoral of the opposite limb, both treated by ligature, 521
Hunyadvur, Dr. Arányi von, death of, 385
Hutchinson, Dr. J. D., death of, 277
——, Mr. J., on adenoma of mammæ, with supervention of scirrhus, 1016; on arsenic cancer, 1166
——, Mr. J., jun., on ophthalmoplegia, 115
Hydatid tumour, myelitis from a, 726
Hydrastis, uterine myoma treated with, 1287
Hydrocele, a radical cure of, 515
Hydrocephalus as a complication of labour, 963
Hydrochlorate of apomorphine, 497
Hydrochloric acid in gastric juice, 1133
Hydronephrosis, nephrectomy, for, 66; congenital, 1015
Hydrophobia, report of the committee on Pasteur's method, 21, 23; Pasteur's system of preventive treatment of, 44, 1168; question, the, 235; a case of, death, necropsy, 311; deaths from, 666, 993, 1095, 1192; cases of, in Liverpool, 674, 737, 791; cure of, in Belfast, 940; and tetanus, cases of, 363
Hydrophobic virus destroyer, 1293
Hygiene, the International Congress of, 224, 432, 541, 683, 724, 734, 767, 837, 936; prizes for pamphlets on, 313; in French schools, 347; in the schoolroom, 630
Hygienic protector under-vest, the, 1119
Hypertrichosis, lumbar, a case of, 1063
Hypertrophy of the lingual tonsil, 1311
Hypnotism, M. Luys, on, 547; before the French law, 1147
Hypodermic injections of chloride of sodium in collapse, 1288
Hypophosphites, compound syrup of, 265
Hysterectomy, vaginal, 238, 811; supra-vaginal, 964
Hysteria and traumatism, 577
Hysterical hyperpyrexia, 1112
Hysterical religion, 536
—— spasm simulating tetany, case of, 439
—— tremor and contracture, 1113
Hystero-epilepsy, cured by a sham operation, 726; successfully treated by removal of damaged uterine appendages, case of, 1213
Hystero-saturnine paralysis, 768

Ichthyol, 1136
Icthyosis hystrix nigricans, 429
Icterus neonatorum, 776
Ikin, Mr. J. I., in memoriam, 397
Ilfracombe, the climate of, 145; disaster, the, 493, 583; health of, 1141
Ilkley, urban district, health of, 38
Illustrations (review), 1318
Imbeciles, homes for, of limited means, 397
Imperforate anus, 565
Impotence and diabetes, 1253
Incurables, Hospital for, 42, 1025
Index finger, dislocation backwards of the first phalanx of the, 351
India, a trip to, 327; hospitals for women in, 349; medical officers in, 349, 549; the Contagious Diseases Acts in, 529; the Government of, and the drink question, 677; sewers in, 682; report on sanitary measures in, in 1885-6, 881
Indian lady doctors and their fees, 632
—— women, a future for, 430
In-door pupils, 244
Induction balance, case illustrating the value of the, for detecting a needle in the thumb, 215
Inebriates, homes for, of limited means, 897, 948
Inebriety, colonial and international congress on, 70; Society for the Study of, 718, 1044, 1173; the disease of, and its treatment, 1010; medical jurisprudence of, 1280
Infant life insurance, 194
—— mortality, 395; in England and in France, 670
Infantile diarrhœa, 693; the cause of, 428
Infants, intestinal affections of young, 1337
Infectious cases, accommodation for, a suggestion, 373
—— diseases, notification of, 82, 682, 718, 727, 773, 785, 835, 878, 887, 1189, 1239; hospitals for, 185, 736; the prevention of, 979; common to man and the lower animals, 1186, 1240
—— paupers, the isolation of, 625; important decision as to the isolation of, 1080
Influence of Sex in Disease (review), 1317
Ingham, measles at, 1347
Ingluvin, 86
Inguinal aneurysm successfully treated by ligature of the external iliac, with popliteal aneurysm in the opposite limb, treated by compression and galvano-puncture, 414
Inhalation, and the lack of precision in the method of using it, 106
Inherited syphilis, micro-organisms in, 771
Inquest extraordinary, 1080, 1152, 1202
Insane, useful employment in the treatment of the, 392, 436; general paralysis of the, onset in form of stupor, apparent recovery, relapse with expansive delirium, and speedy death, 960
Instrument cases, improvement in, 919
Interesting problem, an, 1134
International Congress on Cremation, 385
—— Congress of Hygiene, 224, 432, 541, 683, 724, 734, 767, 837, 936
—— Medical Congress, 327, 378, 570, 617; programme of sections, 501; summary of proceedings, 526, 538; social aspects of the, 627
—— Shorthand Congress, 640
Intestinal affections of young infants, 1337
—— obstruction, cases of, illustrating some possible errors of diagnosis, 255; chronic, the, diagnosis and treatment of, 851, 861; caused by strangulation of a diaphragmatic hernia, necropsy, 912; due to impacted gall-stone, the treatment of, 1192
—— surgery, 723; an experimental contribution to, 708
Intestine, the condition and management of the, after abdominal section, 860; small, case of perforation of an ulcer of, due to a fall, associated with fracture of four ribs by direct violence, 859; stricture of, following tubercular ulceration, 1166
Intra-laryngeal abscess, idiopathic, 609
Introductories, the, 719
Intussusception, 1272
Ipecacuanha, the cultivation of, 294

SAWYER, Sir J.:—
Clinical Lecture on the Treatment of Gastralgia, 299

STEVEN, Dr. J. L.:—
Lectures on Fibroid Degeneration and Allied Lesions of the Heart, and their Association with Disease of the Coronary Arteries.
Lecture I., 1153
Lecture II., 1205
Lecture III., 1255, 1305

STOKES, Sir W.:—
Inaugural Address on Work done in Surgery by its Professors in the Royal College of Surgeons in Ireland, delivered at the opening of the School of Surgery, Royal College of Surgeons, session 1887-88, 899

STONE, Mr. W. H.:—
The Harveian Oration, delivered at the Royal College of Physicians, Oct. 18th, 1887, 797

STURGES, Dr. O.:—
Introductory Address, delivered at Westminster Hospital at the opening of the winter session 1887-88, 697

SUTTON, Mr. J. B.:—
Clinical Lecture (Abstract of a) on Spina Bifida Occulta, and its relation to Ulcus Perforans and Pes Varus, 4

TAYLOR, Dr. C. B.:—
Clinical Lectures on Diseases of the Eye delivered at the Nottingham and Midland Eye Infirmary.
Lecture VI., 505, 1257

TREVES, Mr. F.:—
Clinical Lecture on a Case of Removal of the Kidney together with both Ovaries, 603

WEST, Dr. S.:—
The Bradshawe Lecture on Pneumotho rax delivered at the Royal College of Physici ans 335

Ledgard, Mr. W. B., on a remarkable case of longevity, 947
Lediard, Dr. H. A., on molluscum fibrosum and large pendulous fibroma, 62; recovery from bullet wound of liver, 813
Lee, Mr. H., on the functions of the fourth pair of nerves, 9
——, Mr. S., on treatment of scarlet fever, 786; on the waste of life by preventable disease, 795
Leech, Professor, address on sparteine, 319
Leeds, Royal Infirmary of, sad accident to nurses of, 46; workpeople's jubilee gift, 93
Leg, two cases of elephantiasis of the, in one of which the femoral artery was ligatured, 16
Legal medicine, practical lectures on, 399, 902
Leicester, rabies at, 94; sanitation at, 227; urban district, health of, 284; and vaccination, 622, 678; protected by vaccination, 720, 769, 794, 833, 878, 897; small-pox at, 1128, 1234; and Leicestershire Provident Dispensary, 1281
Lemonette, 765
Lenses, traumatic dislocation of both, 1315
Lepra, micro-organisms of, 372
Leprosy, the prevention of, by segregation, 429; spread of, 842, 980; non-tuberculated, with local asphyxia between the anæsthetic patches, 958
Letts's Medical Ledger and Diaries (review), 1070, 1225
Leucin and tyrosin, 323
Leucoplakia of tongue, 1315
Lewers, Dr. A. H. N., on rapid dilatation of the cervix uteri, 507
Lewis, Mr. D., on removal of a breast tumour with the aid of cocaine, 199
Lewtas, Mr. J., on acute ascending paralysis, 310
Life, the waste of, by preventable disease, 795
Lightning, cold affusion in apparent death from, 673
Lime, treatment of cancer by the administration of, 682
Lindsay, Dr. J. A., the Climatic Treatment of Consumption (review), 220
Lingual "hemiplegia," 772
—— tonsil, the, 139; hypertrophy of the, use of galvano-cautery, recovery, 1311
Liniment, for club use, 898, 948
Linnell, the case of, 1236
Liouville, Dr., the death of, 83
Lippincott, Dr. G. C., on pain and its interpretation, 594
Lipski, Israel, the case of, 378, 428, 441
Liquor amnii and fœtal nourishment, 1185
—— podophyllin et pepsin, 765; et belladonna c. strychine, ib.
Lisburn, County Antrim Infirmary, 141
Literary announcements, 894, 943
Litholapaxy in boys, 317
Lithotomy, supra-pubic, 112, 811; a historical sketch, 1104; lateral and supra-pubic, a case of combined, 416
—— position, apparatus for maintaining the, 765
Liveing, Dr. R., a Handbook of Diseases of the Skin, with especial reference to Diagnosis and Treatment (review), 664
Liver, the, abscess of, in a child three years and a half old, 310; chronic hypertrophic cirrhosis of, 413; abscess of, operation, recovery, 660; bullet wound of, recovery from, 813; lævorotatory sugar in the, 828; experimental hæmorrhagic infarction of, 915; hydatid disease of the, 1214, 1219; in phosphorus poisoning, 1272
LIVERPOOL.—Cellar dwellings in Liverpool; infectious hospitals accommodation; removals to mortuaries; sanitary work in Liverpool during 1886, 138—The rebuilding of the Royal Infirmary; the old infirmary; the present infirmary; the proposed new infirmary; Hospital Sunday and Saturday Fund, 239; the summer assizes; river pollution; conversion of another city churchyard into a recreation ground; the holiday season, 393—Enlargement of Bootle Hospital; the Saturday half-holiday; the mixture of drugs; chewing gum, 546—The gymnasium; emptying ashpits and diarrhœa; narrow escape of firemen; deaths from hydrophobia, 636, 737, 1192—Scarlatina at the School for the Deaf and Dumb; University College, 737—The Medical Institute; Royal southern Hospital; City hospitals for infectious disease, 890—Hospital Saturday and Sunday; the Hospital for Women ib., 1092—Interesting abdominal section; the Northern Hospital, 988—The Mayor and the hospitals; death of a ship-captain from laudanum; the assizes; extra-uterine gestation, 1092—Popular lectures; City meat supply; the late Mr. Edw. Parker; the Eye and Ear Hospitals; flogging garotters, 1193—Lord Wolseley on athletics; the police and night duty, 1295
Liverpool, health of, 88; a blunder at, 130; correspondence from, 138, *passim*; sanitary work in, during 1886, ib.; cellar dwellings in, ib.; Hospital Sunday and Saturday Fund, 240, 988; recreation grounds in, 393; gymnasium at, 636; deaths from hydrophobia at, 674, 791; scarlatina at a school for deaf and dumb, 737; the Mayor of, and the hospitals, 1092; the assizes at, ib.; meat supply of, 1193
—— Eye and Ear Infirmary, 1193
—— Hospital for Women, 988, 1092
——, infectious hospitals, accommodation at, 138, 890, 921
—— Medical Institution, 890
—— Royal Infirmary, 737, 925, 1295; the rebuilding of the, 239; the old infirmary, 239; the present infirmary, 239
—— University College, the medical faculty of the, 737; popular lectures at, 1192
Local Government Board, annual report of the, 573, 1318
Lock hospitals or lock wards for women, Government grants to, 377
Lock's beef extract, 765
Lockwood, Mr. C. B., the honours examinations of the University of London, 886
Locomotor ataxia, 1116; the early signs of, 380
"Locums," the registration of, 335
London, medical students, degrees for, 21, 177, 867, 1288, 1291, 1331; the sewage of, 286, 390; fires, 336, 447; the Thames as a water supply for, 337; infectious disease in, 382; hospitals in, gratuitous advice at, 544; water supply of, 585; fever epidemic in, 425, 532, 876, 926, 975, 1034, 1077, 1133, 1181, 1236, 1280; proposals for a new university in, 1175, 1278; the port of, 1238; fever in, 1338
—— Hospital, réunion at, 729
—— Temperance Hospital, 1250, 1348
—— University, 1136; honours examinations at the, 833, 885, 923, 1347
Londonderry, small-pox epidemic in, 941
Long, Dr. M., on the duration of scarlet fever infection, 733
Longevity, remarkable case of, 947
Lord Mayor, the anti-vaccinationists and the, 1033
"Lords and ladies," poisoning by, 231
Love, Mr. J. H., on spina bifida, accompanied with congenital malformation of the cervical portion of the spinal canal, 1216
Lower Thames valley, drainage scheme in the, 525

MIRROR OF HOSPITAL PRACTICE, BRITISH AND FOREIGN.

ADEN CIVIL HOSPITAL.—Two cases of perforating wound of the abdomen, with protrusion of intestine; recovery, 914—Urinary fistula; operation; relief, ib.

ANTRIM COUNTY INFIRMARY, LISBURN.—Cerebral abscess, following wound of scalp; trephining; death, 522

AYR COUNTY HOSPITAL.—Herniotomy twice within three months, 614—Necrosis of rib, ib.—Amputation of arm in an old man, ib.—Immense hypertrophy of heart, ib.

BATH EASTERN DISPENSARY. — Malignant disease of the œsophagus; relief by gastrostomy; death twenty-eight days after the stomach was opened, 711

BIRMINGHAM GENERAL HOSPITAL.—Aneurysm of the superficial femoral artery in Hunter's canal, preceded by aneurysm of the common femoral of the opposite limb, both treated by ligature, 521

BRIGHTON AND HOVE LYING-IN INSTITUTION.—Delivery of a child at full time, four years and a half after amputation of the cervix for prolapse, 1068

BRISTOL GENERAL HOSPITAL.—A case of suprapubic lithotomy, and one of supra-vaginal hysterectomy, 811

CHARING-CROSS HOSPITAL.—Acute ulcerative endocarditis; death in eight days; necropsy, 368

CHESTER GENERAL INFIRMARY.—Large strangulated umbilical hernia; operation; death necropsy, 1165

CITY OF LONDON INFIRMARY.—Retention of urine preceding apoplectic attacks, 1014

CROMER COTTAGE HOSPITAL.—Chronic empyema, treated by Estlander's method; cure, 312

CUMBERLAND INFIRMARY.—Peritoneal abscess discharging through the umbilicus, 262

DEVON AND EXETER HOSPITAL.—Three cases of compound fracture of skull; trephining; recovery, 416

DUNDEE ROYAL INFIRMARY.—Suppurative gastritis; death; necropsy, 1166

EDINBURGH ROYAL INFIRMARY.—Simple fracture of femur with rupture of popliteal artery and vein; amputation through thigh, 17—Four rare forms of dislocation, 913

GLASGOW MATERNITY HOSPITAL.—Hemiplegia during the puerperium, 661

GLASGOW ROYAL INFIRMARY.—Herniotomy; gangrene of intestine; resection of bowel; enterroraphy; recovery, 521

GREAT NORTHERN CENTRAL HOSPITAL.—Disease of hip-joint; excision of head of femur; subsequent removal of great trochanter; good result, 810

GUY'S HOSPITAL.—Epithelioma of the lip and glands; recurrence after removal; excision of the growth with two inches of the internal jugular vein; exposure of the deep vessels and nerves; pneumogastric symptoms; recovery, 1312

HALIFAX INFIRMARY.—Purulent discharge from the ear, followed by diffuse suppurative meningitis; death; necropsy, 312

HOSPITAL FOR SICK CHILDREN.—Two cases of calculus; operation, 809—Two cases of disease of the tibia in which the knee joint was involved in acute suppuration; conservation; recovery, 1266

JULLUNDUR STATION HOSPITAL.—Fatal case of external urethrotomy, 614

KIDDERMINSTER INFIRMARY AND CHILDREN'S HOSPITAL.—Gastrostomy in a case of malignant stricture of the œsophagus; death; necropsy, 114

LEEDS GENERAL INFIRMARY.—Multiple abnormal synovial cysts around the knee, 114

LEICESTER INFIRMARY.—Vomiting of gallstones; death; necropsy, 961

LIVERPOOL INFIRMARY. — Cerebellar abscess; death; necropsy, 168

LIVERPOOL ROYAL SOUTHERN HOSPITAL.—Incised and penetrating wound of abdomen, with partial division of small intestine; puncture of sigmoid flexure in one, and of mesentery in five places; copious hæmorrhage; collapse; death; necropsy, 567

LONDON HOSPITAL.—Disease of ankle joint; excision of astragalus, 15—Compound fracture into ankle joint; operation, ib.—dislocation of astragalus, ib.—Compound dislocation of the elbow joint; excision; suture of ulnar nerve, 166—Removal of loose body from knee joint, 167 — Post-acromial dislocation of humerus, ib.—An unusual case of scirrhus of the breast, 520—Gastrostomy for œsophageal obstruction, with successful result, 859—Primary cancer of female bladder; ovarian cystomata; growth removed by vaginal cystotomy; fresh growth again removed by a second operation; recurrence; secondary

Digitized by Google

growths in other organs; third operation; death, 1164
MANCHESTER ROYAL INFIRMARY.—Combined lateral and supra-pubic lithotomy, 416—Rupture of rectum; peritonitis; necropsy, with discovery of a piece of cloth in the abdominal cavity, 1110
MIDDLESEX HOSPITAL.—Two cases of disease of the thyroid; one treated by excision, the other by injection of iodine; recovery, 613—Three fatal cases of non-tropical dysentery, 709—A series of renal cases, 1012, 1054
NEWCASTLE-ON-TYNE INFIRMARY.—Elephantiasis of leg; ligature of femoral artery, 16—Three cases of compound fracture of the skull; trephining; recovery, 216
NORTH LONDON HOSPITAL FOR CONSUMPTION.—Empyema of four years' duration treated by incision and drainage; melancholia, 566
OLDHAM INFIRMARY.—Pseudo-hypertrophic muscular paralysis in its first stage, or progressive multiple neuritis; recovery, 758
PADDINGTON INFIRMARY.—Abscess of liver; operation; recovery, 660
PORTSMOUTH BOROUGH LUNATIC ASYLUM.—General paralysis of the insane; onset in form of stupor; apparent recovery; relapse, with expansive delirium and speedy death, 960
ST. BARTHOLOMEW'S HOSPITAL.—Two cases of fracture of spine with displacement: in one, death after recurrent attacks of erysipelas; in the other, recovery after extension under anæsthetic, 261
ST. BARTHOLOMEW'S HOSPITAL, CHATHAM—Four cases of amputation through the thigh, 1217
ST. MARY'S HOSPITAL.—Operation for the radical cure of strangulated inguinal hernia; removal of atrophied testis; recovery, 959—Postero-parietal depressed fracture; high temperature; trephining, 1216
ST. THOMAS'S HOSPITAL.—Two cases of papilloma of the bladder removed by the wire écraseur: in one (male) by supra-pubic cystotomy; in the other (female) by the urethra; cure, 65—A case of hydrophobia; death; necropsy, 311—Inguinal aneurysm successfully treated by ligature of external iliac artery; popliteal aneurysm in opposite limb, treated by compression and galvano-puncture; necropsy, eighteen months after operation, 414—Acute peritonitis from perforation of an ulcer of the gall-bladder; necropsy, 912—Intestinal obstruction caused by strangulation of a diaphragmatic hernia; necropsy, 913
SAMARITAN HOSPITAL FOR WOMEN, NOTTINGHAM.—Nephrectomy for hydronephrosis, 66—Radical cure of umbilical hernia, 160
STANLEY HOSPITAL, LIVERPOOL.—Dislocation of the hip in a child aged five, 117
UNIVERSITY COLLEGE HOSPITAL.—Scirrhus of the pancreas, causing intestinal obstruction; colotomy; death; necropsy, 113—Epithelioma of tongue and glands; removal by Kocher's method; patient fed for a fortnight through a tube retained in the wound; complete recovery, 758—Removal of part of jaw, tongue, side of pharynx, and soft palate for epithelioma, 1110
WEST HERTS INFIRMARY.—Ankylosis of knee-joint, 1267—Vesical calculus; supra-pubic lithotomy, ib.—Gunshot-wounds of shoulder and of face, 1314—Genu valgum on both sides; osteotomy on the left side; cure, ib.
WEST KENT GENERAL HOSPITAL.—Stricture of œsophagus; gastrostomy; death four months after operation; necropsy, 369
WESTMINSTER HOSPITAL.—Case illustrating the value of the induction balance for detecting a needle in the thumb, 215
WINDSOR STATION HOSPITAL.—Fracture of the fifth cervical vertebra, with compression of the spinal cord; duration of life ten months, 661
WOLVERHAMPTON GENERAL HOSPITAL.—Aneurysm of coronary artery; rupture; necropsy, 67
WOLVERHAMPTON AND STAFFORDSHIRE INFIRMARY.—Epithelioma of penis and scrotum, with enlarged inguinal glands; complete removal of external genitals; recovery, 370
WORCESTER GENERAL INFIRMARY.—Perforation of an ulcer of small intestine due to a fall, associated with fracture of four ribs by direct violence, 859—Compound depressed fracture of skull; operation; recovery, 1111
